## FROGSSTAT with Phyloseq R package

R package (McMurdie and Holmes, 2013) to analyse community composition data in a phylogenetic framework

It uses other R packages:

- Community ecology functions from vegan, ade4
- Tree manipulation from ape
- Graphics from ggplot2
- Differential analysis from DESeq2

→ At the end of FROGS pipeline, what kind of data do we have ?

→ At the end of FROGS pipeline, what kind of data do we have ?

FROGS biom containing:

- ASV count tables (required)
- ASV description : taxonomy

Phylogenetic tree in Newick format

Metadata: sample description in TSV file

→ Take a look at the metadata

→ Take a look at the metadata

FoodType:

Meat or Seafood

EnvType: 8 environment types

EnvType Description FoodType Description FoodType EnvType DLT0.LOT01 DesLardons LOT1 Meat DLT0.LOT03 DesLardons LOT3 Meat DLT0.LOT04 LOT4 DesLardons Meat DLT0.LOT05 LOT5 DesLardons Meat DLT0.LOT06 DesLardons LOT6 Meat DLT0.LOT07 DesLardons LOT7 Meat DLT0.LOT08 LOT8 DesLardons Meat DLT0.LOT10 DesLardons LOT10 Meat MVT0.LOT01 MerguezVolaille LOT1 Meat MVT0.LOT03 MerguezVolaille LOT3 Meat MVT0.LOT05 MerguezVolaille LOT5 Meat MVT0.LOT06 MerguezVolaille Meat LOT6 MVT0.LOT07 MerguezVolaille LOT7 Meat MVT0.LOT08 MerguezVolaille LOT8 Meat MVT0.LOT09 MerguezVolaille LOT9 Meat MVT0.LOT10 MerguezVolaille LOT10 Meat BHT0.LOT01 **BoeufHache** LOT1 Meat BHT0.LOT03 BoeufHache LOT3 Meat

# Phyloseq Import Data tool

PHYLOSEQ OBJECT CREATION

## Phyloseq : Data import

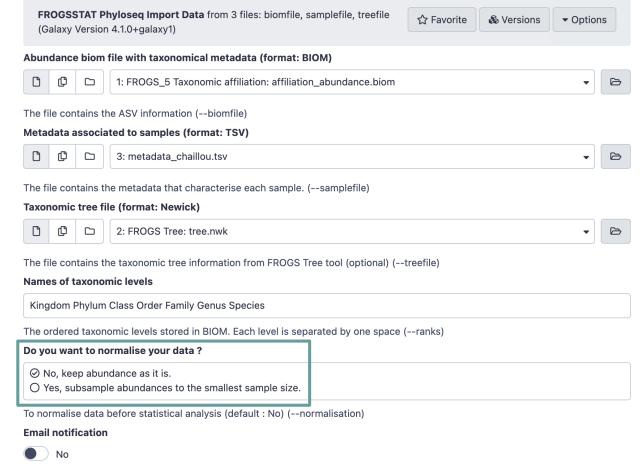

- 1. Statistical analysis is done in R, so an R object called Rdata must be created.
- 2. Run PhyloSeq Data import

The FROGS biom format contains:

- ASV count tables (required)
- ASV description : taxonomy

Others information used in FROGSSTAT are:

- sample description in TSV file
- phylogenetic tree in Newick format (nwk or nhx)
- 3. Create 2 phyloseq objects, with and without normalization (rename them)

Send an email notification when the job completes

🗸 Execute

1. What are the resulting datasets ?

2. What is the difference between the resulting objects with and without normalization ?

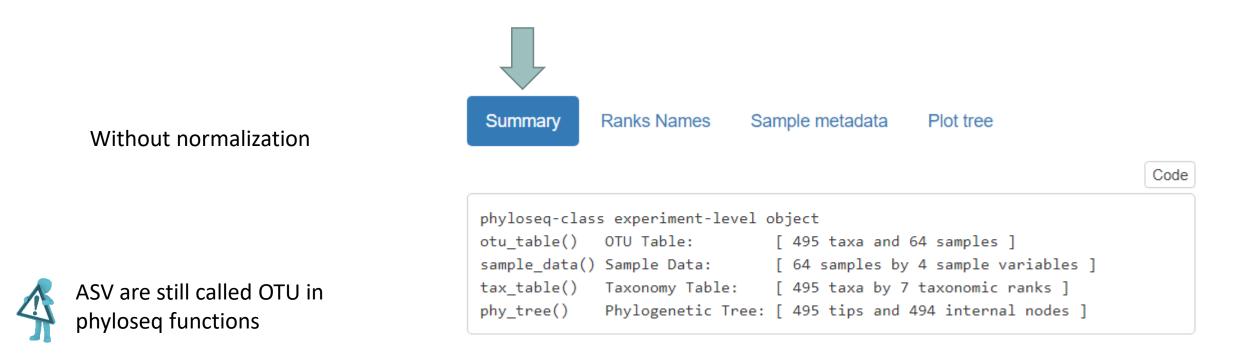

3. Explore the HTML results

1. What are the resulting datasets ?

 $\rightarrow$  asv\_data.Rdata file: R object used by phyloseq package for statistics

 $\rightarrow$  HTML report: summary of the phyloseq object

2. What is the difference between the resulting objects with and without normalization ?

2. What is the difference between the resulting objects with and without normalization?

Taxonomic level used for aggregation         Phylum         Ex: Family (when filtering at the Phylum level). The aggregation level must be below the filtering level         Number of most abundant taxa to keep			parameters	
9 Ex: 9, i.e. Tool keeps the 9 most abundant taxa and the remaining taxa are aggregated in a group -K	Number of majority gro displayed	oupings to be		22

- 1. What are the resulting datasets ?
- 2. What is the difference between Bar plot and Plot composition ?
- 3. What biological information could you extract ?
- 4. What are the perspectives for going further?

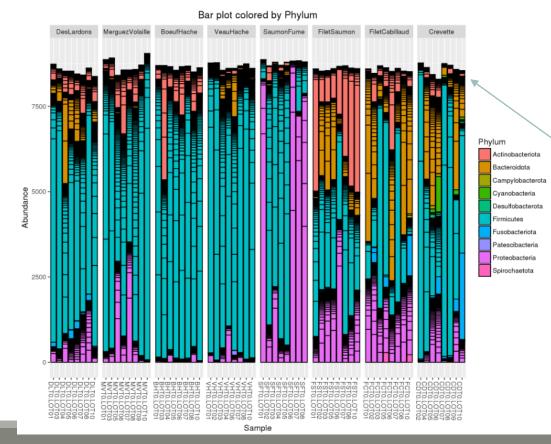

1. What are the resulting datasets ?

 $\rightarrow$  HTML report: summary of the phyloseq object

- Bar plot
- Composition plot

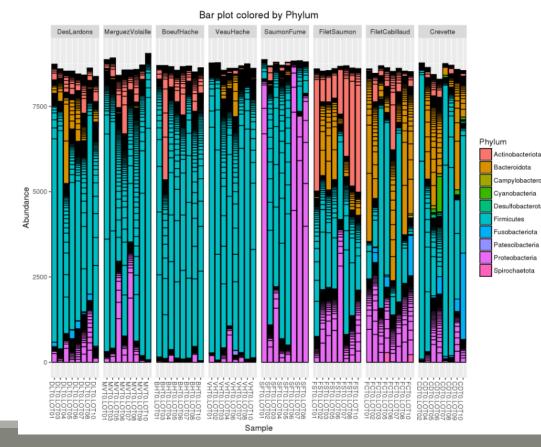

#### 2. What is the difference between Bar plot and Plot composition ?

- one rectangle is one ASV
- one color is one phylum
- y axis: number of sequences these are absolute counts
- size of rectangle depends on number of sequences

#### 2. What is the difference between Bar plot and Plot composition ?

#### Limitations:

- Plot bar works at the ASV-level and displays all the ASV at the specified rank
- This may lead to cluttered graphics and unnecessary legends
- No easy way to look at a subset of the data
- Works with absolute counts (beware of unequal depths or used normalized function)

### Exploring biodiversity : visualization

Another graph: plot\_composition function :

- Works with **relative abundances**
- Subsets ASVs at a given taxonomic level

#### Taxonomic level to filter your data

#### Kingdom

ex: Kingdom, Phylum, Class, Order, Family, Genus, Species

#### Taxa (at the above taxonomic level) to keep in the dataset

#### Bacteria

ex: Bacteria (when filtering at the Kingdom level), Firmicutes (when filtering at the Phylum level). Multiple taxa (separated by a space) can be specified, i.e. Firmicutes Proteobacteria

#### Taxonomic level used for aggregation

Aggregates ASVs at another taxonomic level	Phylum
	ex: Family (when filtering at the Phylum level). The aggregation level must be below the filtering level

#### Number of most abundant taxa to keep

9

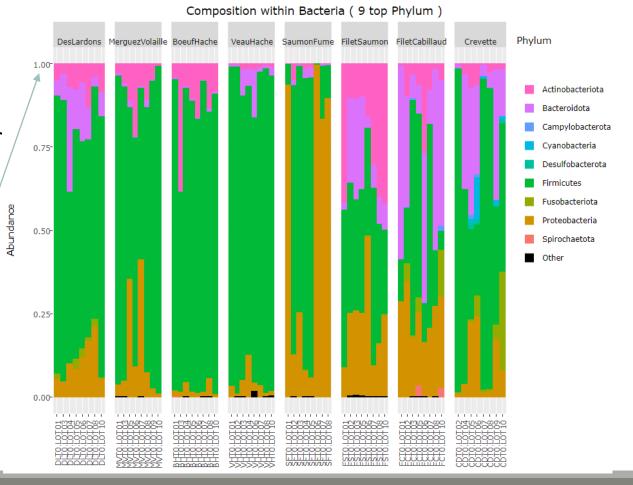

ex: 9, i.e. Tool keeps the 9 most abundant taxa and the remaining taxa are aggregated in a group 'Other'

Shows only a given number of taxa

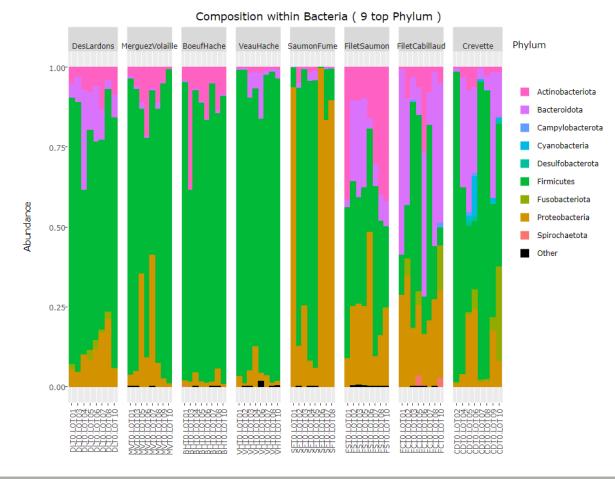

Composition plot

#### Bar plot

- 2. What is the difference between Bar plot and Plot composition ?
- one rectangle is one phylum (no borderline) (or any other specified taxonomy rank)
- one color is one phylum
- y axis: counts are reduced to 1, so, here, we have relative counts

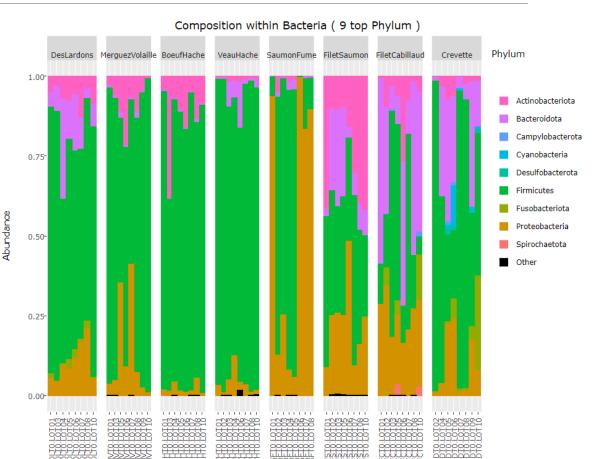

3. What biological information could you extract?

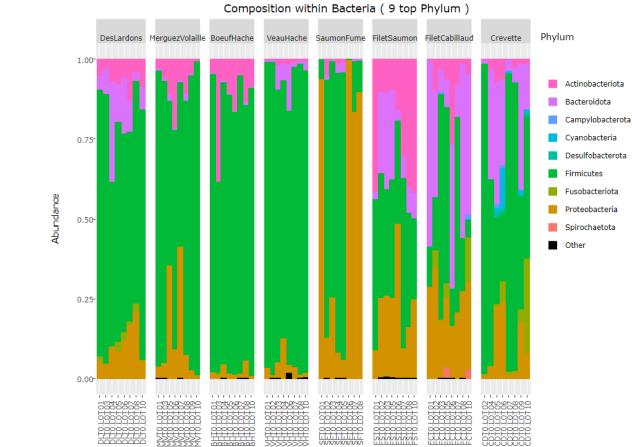

3. What biological information could you extract ?

Exercise 3

- Meat types on the left share common Phylum composition, with a majority of Firmicutes (easy to remark thanks of ordered levels)
- Seafoods seem to be much more variable
- Firmicutes and Proteobacteria are present in all samples, but with a wide range of abundance

#### Composition plot Bar plot

งเง่นงานการ

uuuu

4. What are the perspectives for going further?

**Exercise 3** 

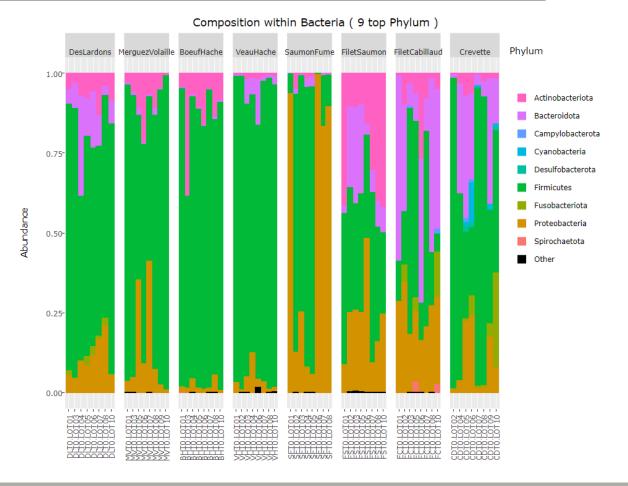

- Fusobacteriota Proteobacteria Spirochaetota

#### Bar plot Composition plot

### Exercise 3

4. What are the perspectives for going further?

- ➔ What is the composition of the 9 most abundant Families of *Firmicutes* ?
- → What is the composition of the 9 most abundant Families of *Proteobacteria* ?

1. What is the composition of the 9 most abundant Families of Firmicutes ?

2. What is the composition of the 9 most abundant Families of Proteobacteria ?

### 1. What is the composition of the 9 most abundant Families of Firmicutes ?

#### Taxonomic level to filter your data

Phylum

ex: Kingdom, Phylum, Class, Order, Family, Genus, Species

Taxa (at the above taxonomic level) to keep in the dataset

Firmicutes

ex: Bacteria (when filtering at the Kingdom level), Firmicutes (when filtering at the Phylum level). Multiple taxa (separated by a space) can be specified, i.e. Firmicutes Proteobacteria

#### Taxonomic level used for aggregation

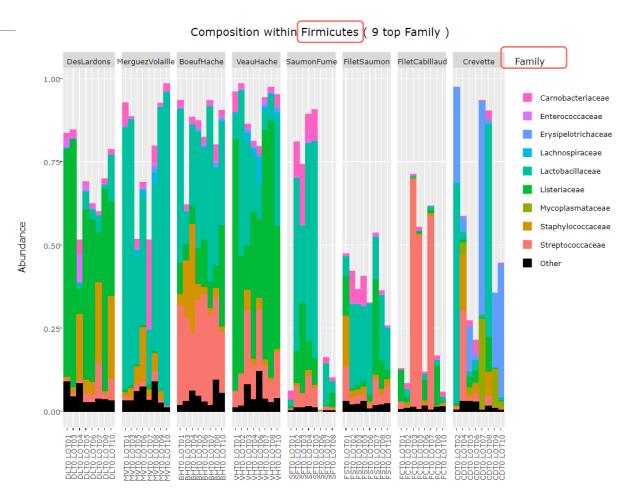

Family

ex: Family (when filtering at the Phylum level). The aggregation level must be below the filtering level.

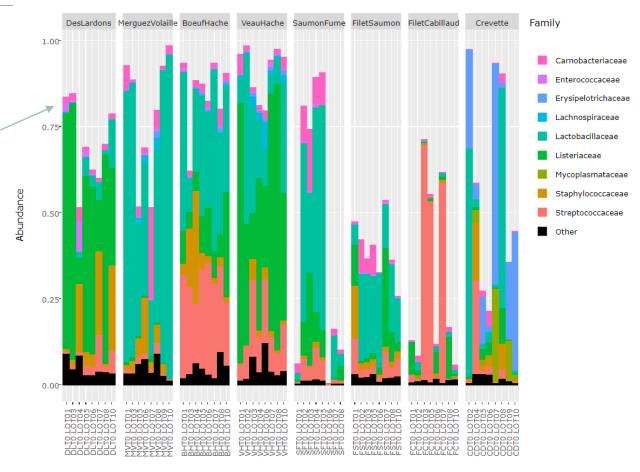

#### Number of most abundant taxa to keep

9

ex: 9, i.e. Tool keeps the 9 most abundant taxa and the remaining taxa are aggregated in a group 'Other'

- What is the composition of the 9 most abundant Families of Firmicutes ?
  - Abundance does not reach 1 because only Phylum Firmicutes is displayed, the "missing" abundance is carried by other Phyla.
  - As seen at the Phylum level, Firmicutes are more represented in meat types than in seafoods
  - Dominant Firmicutes families are not the same in each food type

#### Composition within Firmicutes (9 top Family)

#### 2. What is the composition of the 9 most abundant Families of Proteobacteria ?

#### Taxonomic level to filter your data

Phylum
ex: Kingdom, Phylum, Class, Order, Family, Genus, Species
Taxa (at the above taxonomic level) to keep in the dataset
Proteobacteria
ex: Bacteria (when filtering at the Kingdom level), Firmicutes (when filtering at the Phylum level). Multiple taxa (separated by a space) can be specified, i.e. Firmicutes Proteobacteria

#### Taxonomic level used for aggregation

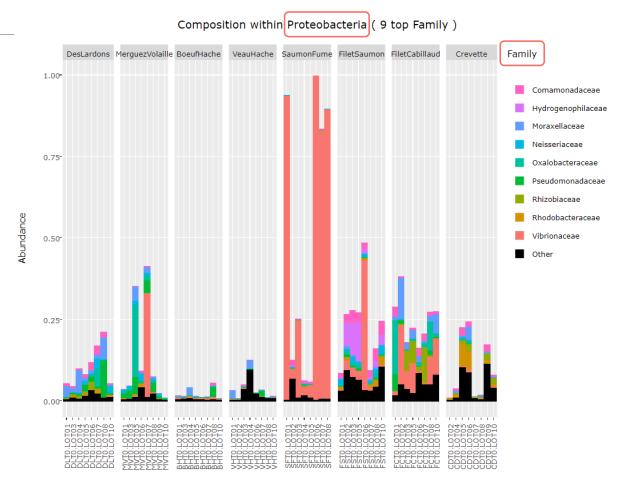

Family

ex: Family (when filtering at the Phylum level). The aggregation level must be below the filtering level.

#### Number of most abundant taxa to keep

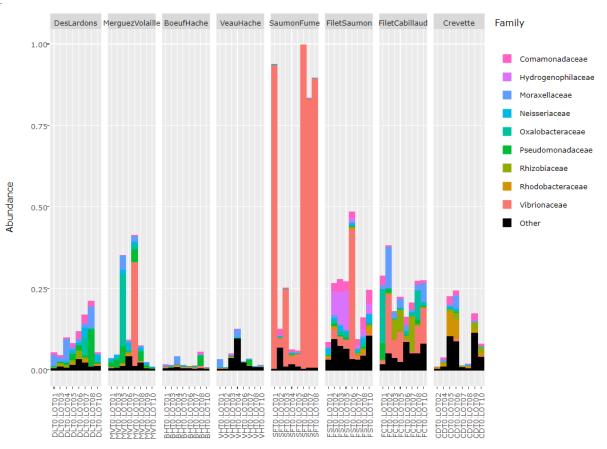

9

ex: 9, i.e. Tool keeps the 9 most abundant taxa and the remaining taxa are aggregated in a group 'Other'

2. What is the composition of the 9 most abundant Families of Proteobacteria ?

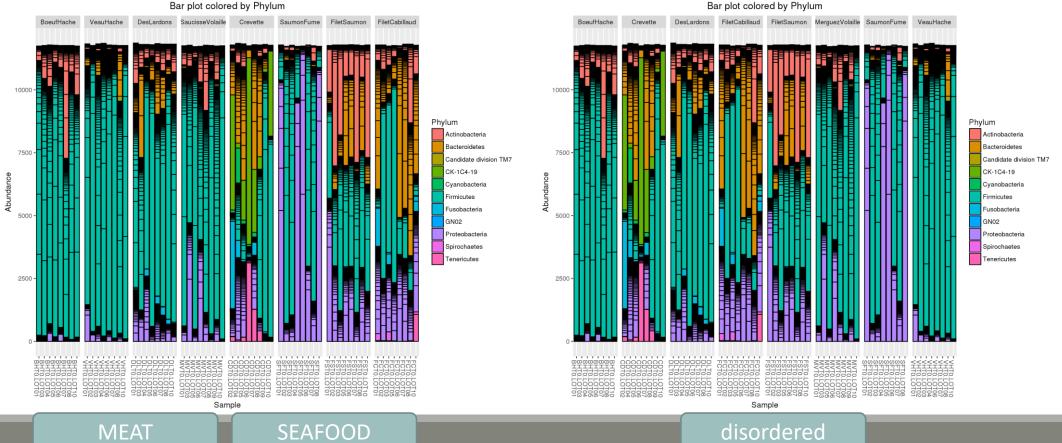

- As seen at the Phylum level, Proteobacteria are particularly present in seafood samples
- SaumonFume samples with extremely high levels of Proteobacteria are dominated by Vibrionaceae family, while other food types are balanced between several families

#### Composition within Proteobacteria ( 9 top Family )

# Exploring biodiversity : visualization

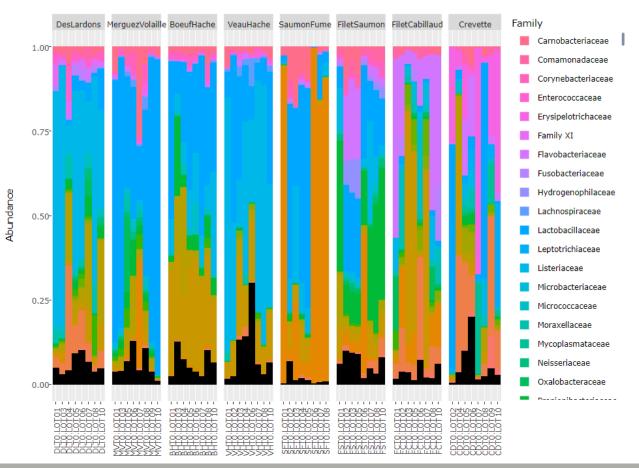

<u>Remark 1</u>: An example of what happens when sample metadata file is not sorted in a meaningful way

# Exploring biodiversity : visualisation

<u>Remark 2</u>: Keep in mind that human eye cannot distinguish more than 12 colors at the same time.

Example of the 30 most abundant Families among Bacteria

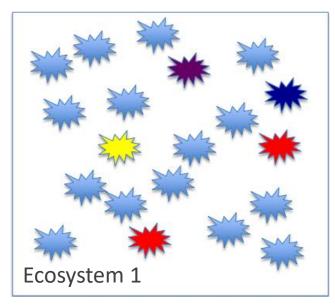

Composition within Bacteria ( 30 top Family )

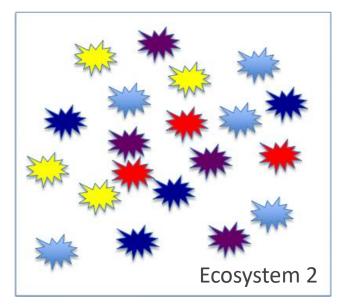

# II. Biodiversity analysis

**DIVERSITY INDICES** 

# Exploring biodiversity : descriptors

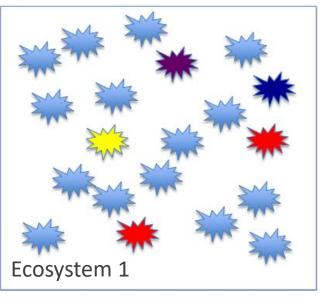

- The richness corresponds to the number of ASVs or functional groups present in communities. It characterizes the composition.
- The **diversity** takes into account the relative abundancy of species. It characterizes the **structure**

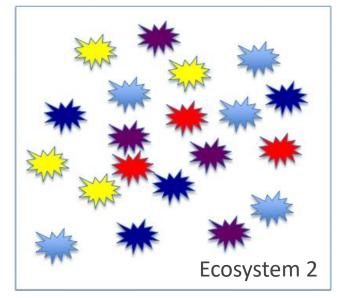

# Exploring biodiversity : descriptors

- The richness corresponds to the number of ASVs or functional groups present in communities. It characterizes the composition.
- The **diversity** takes into account the relative abundancy of species. It characterizes the **structure**

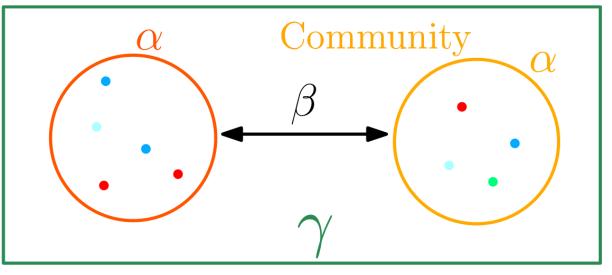

Richness : Eco1 = Eco2 Diversity: Eco2 > Eco1

# Exploring biodiversity : statistical indices

3 levels of diversity:

- **α-diversity**: diversity within a community
- **β-diversity**: diversity between communities
  - β-dissimilarities/distances
    - dissimilarities between pairs of communities
    - often used as a first step to compute diversity
- γ-diversity: diversity at the landscape scale (blurry for bacterial communities)

Landscape

# Exploring biodiversity : statistical indices

There are qualitative, quantitative and phylogenetic indices:

### Qualitative (Presence/Absence) vs. Quantitative (Abundance )

- Qualitative indices give equal weight to all species, dominant or rare
- Qualitative indices are more sensitive to differences in sampling depths
- Qualitative indices emphasize differences in taxa diversity while quantitative are more sensitive to increases in composition differences

### **Phylogenetic indices**

- Require a phylogenetic tree
- phylogeny allows to attenuate clustering errors because 2 different ASVs can be phylogenetically close

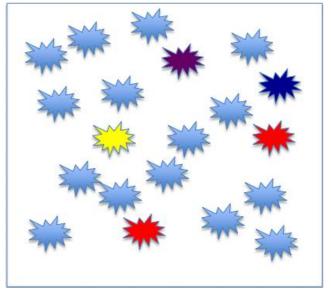

# III. Biodiversity analysis

 $\alpha$ -DIVERSITY INDICES

# $4 \alpha$ -diversity indices

- 1. Richness
- 2. Chao
- 3. Shannon
- 4. Inv-Simpson

### Richness

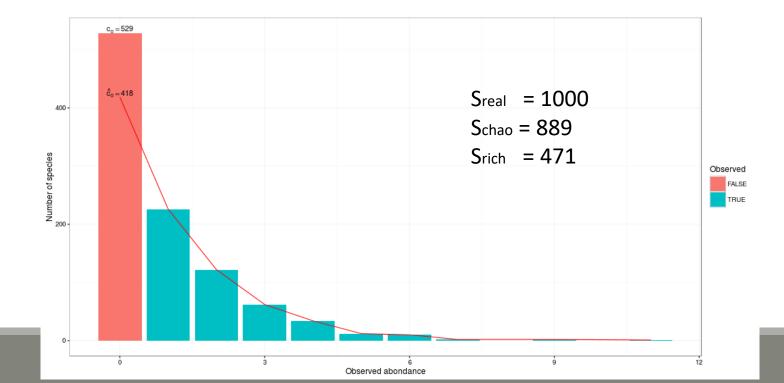

Richness : Eco1 = Eco2

Richness

Number of observed species

## $\alpha$ -diversity: Chao1

Richness	Chao
Number of observed species	Richness + (estimated) number of unobserved species

48

# $\alpha$ -diversity: Chao1

Chao1 is an abundance-based estimator. This means that the data it needs relate to the abundance of taxa in the sample.

This index estimates the number of unobserved species from those that have only been observed once or twice. This diversity index is a minimum estimator. In order for it to fit the dataset, it is necessary that singletons and duplicates represent a significant part of the information

Many taxa, species, are represented by a few individuals (rare species) and others can be represented by many individuals (abundant species).

Well, chao1 is based on the rare species.

So we need to know how many species are represented by 1 individual (singleton) and how many species are represented by 2 individuals (doubletons):

 $S_{est} = S_{obs} + F2/2G$ 

S<sub>est</sub> (nb of species we want to estimate), S<sub>obs</sub> (nb of species observed), F (nb of singletons) and G (nb of doubletons)

If the chao1 is close to the richness  $\rightarrow$  the part of the missed ASVs is low  $\rightarrow$  the sequencing depth is good.

### $\alpha$ -diversity: Chao1

#### Example of a abundance table, after FROGS processing, with ASVs filtering with 0.005% threshold:

singletons and doubletons

 $\rightarrow$  Chao1 computation possible

# $\alpha$ -diversity: Shannon and Inv-Simpson

#### $\alpha$ -diversity is equivalent to the richness : number of species

Shannon	Inv-Simpson
Evenness of the species abundance distribution	Inverse probability that two sequences sampled at random come from the same species

#### Interpretation :

15 observed species, but according to Shannon, the uneven community acts like there is 7.85 equally abundant species (5.45 for invSimp)

### $\alpha$ -diversity indices

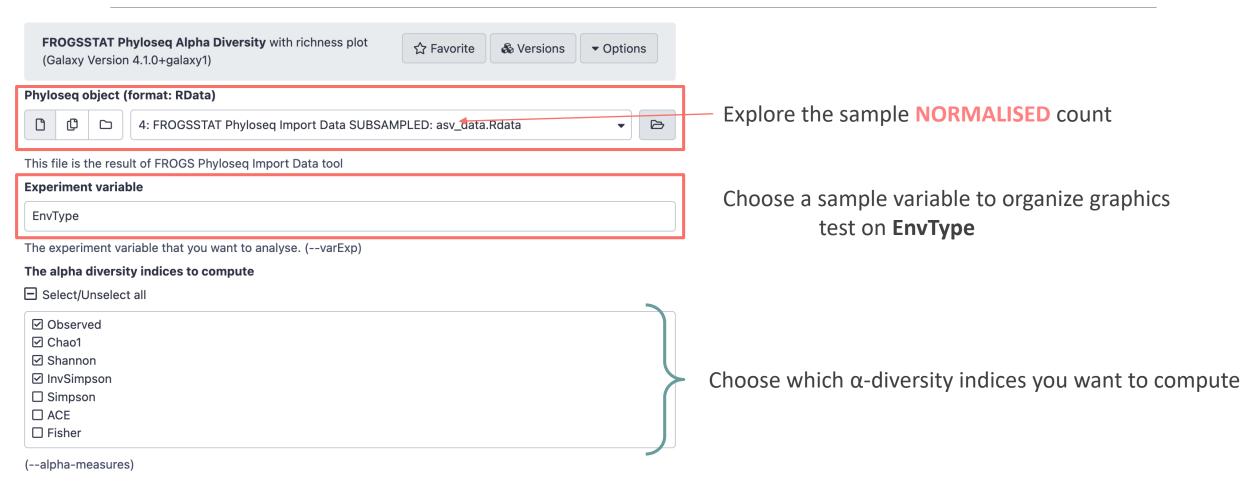

- 1. Chao1 close to Richness  $\rightarrow$  all species have been detected
- 2. higher Shannon index  $\rightarrow$  higher homogeneity  $\rightarrow$  greater diversity
- 3. greater invsimpson index  $\rightarrow$  greater diversity

# Exploring biodiversity : $\alpha$ -diversity

 $\alpha$ -diversity indices available in phyloseq :

- Species richness : number of observed ASV
- Chao1 : number of observed ASV + estimation of the number of unobserved ASV
- Shannon entropy / Jensen : the width of the ASV relative abundance distribution. Roughly, it reflects our (in)ability to predict ASV of a randomly picked bacteria.
- Simpson : 1 probability that two bacteria picked at random in the community belong to different ASV
- Inverse Simpson : inverse of the probability that two bacteria picked at random belong to the same ASV
- Other estimators of alpha diversity exist (Chao2, ACE, ICE,...), however the indices presented above allow us to understand alpha diversity with sufficient precision

# Exploring biodiversity : α-diversity

- 1. What are the output files ?

### 3. Does EnvType has an impact on $\alpha$ -diversity indices ? <u>Anova interpretations</u>

 Environments differ in terms of richness but not in terms of Shannon and InvSimpson diversity

 This means that all EnvTypes have similar structures (equivalent distributions between several minor ASVs and few dominant ASVs). Even if 2 samples of "Crevette" displayed very high invSimpson (their bacteria were thus more homogeneously distributed), these two samples were not sufficient to make "Crevette" significantly different from the others EnvType.

#### There is no significant difference between the EnvType

#### 

#Perform ANOVA on Observed, which effects are significant anova.Observed <-aov( Observed ~ Depth + EnvType, anova\_data) summary(anova.Observed)

**Rarefaction curve interpretations** 

#### **Rarefaction curve interpretations**

- Most of the curves reach a plateau
- A deeper sequencing doesn't add more ASVs
- DesLardons reach the plateau later which correspond to a higher Observed

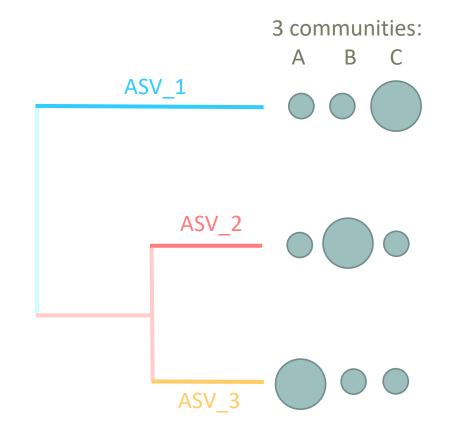

# IV. Biodiversity analysis

 $\beta$ -DIVERSITY INDICES

# Exploring biodiversity : β-diversity

Many diversity indices are available with the Phyloseq package through the generic distance function.

Different dissimilarities capture different features of the communities.

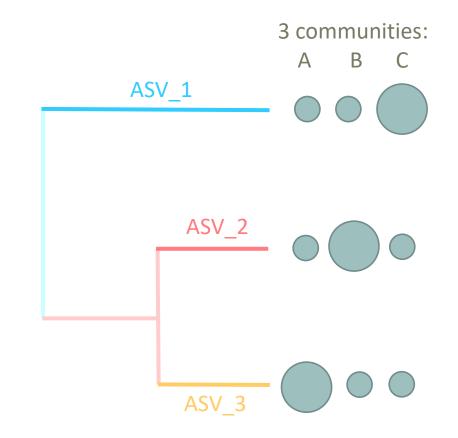

There are different ways to measure beta diversity on a dataset, which give different results.

In this example, 3 ways :

- qualitatively, communities are very similar
- quantitatively, communities are very different
- phylogenetically, two communities seem to be closer than the third one.

Which distance to choose?

 No wrong answer. Each beta-diversity indices will characterize communities differently

If we compare 2 communities A and B:

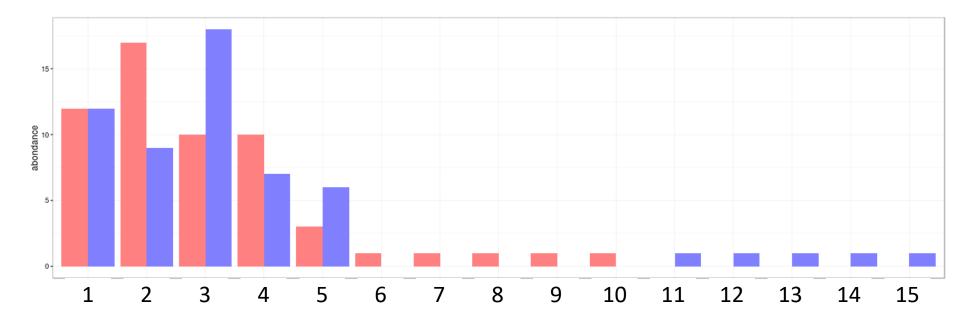

Jaccard index:

• Fraction of <u>species</u> specific to either A or  $B \rightarrow \text{qualitative}$  index

**Bray-Curtis index**:

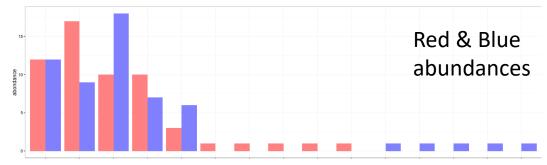

• Fraction of the <u>community</u> specific to either A or  $B \rightarrow quantitative$  index

- 2 communities, Red and Blue
- 15 ASVs with different abundances in Red community and Blue community

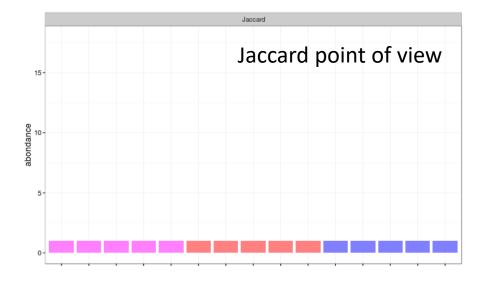

#### Jaccard index:

Proportion of <u>species/ASVs</u> specific to either Red or Blue
 → qualitative index

- Pink = common ASVs between the 2 communities (5)
- Red= ASVs specific to Red community (5)
- Blue= ASVs specific to Blue community (5)

 $D_{jac} = 10/15 = 0.667$ 

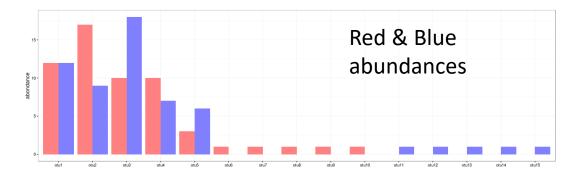

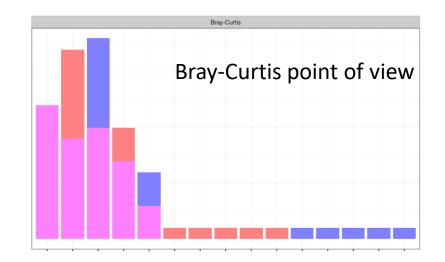

#### **Bray-Curtis index:**

- Proportion of the <u>abundance</u> specific to either Red or Blue → quantitative index
- Ration (sum of specific abundances)/ (total abundances)
- 1<sup>st</sup> ASV does not contribute (same abundance for Red and Blue communities)
- ASV 2, 3, 4 and 5 contribute up to the excess in one of the communities (8+8+3+3+10) in the sum of specific abundances

(Pink is not taken into account in this sum)

 $D_{bc} = (8+8+3+3+10) / (24+26+28+17+9+10) = 0.281$ 

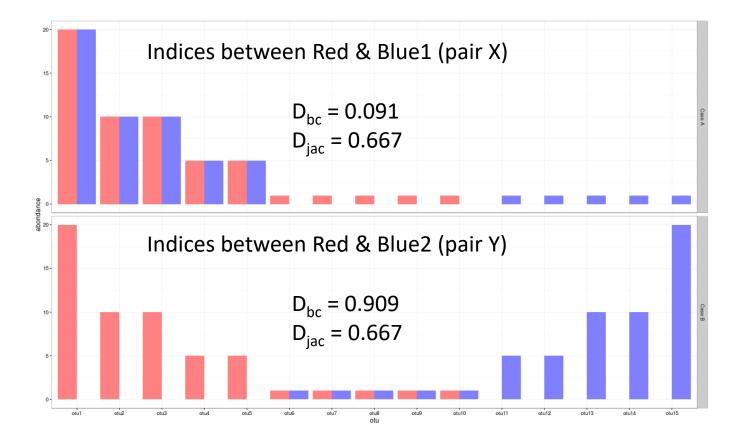

Indices comparison with different distributions:

- between Red & Blue1 communities

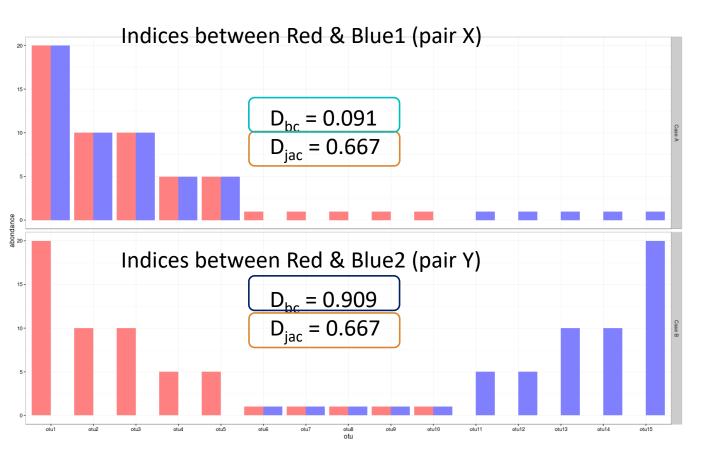

- between Red & Blue2 communities

Jaccard and Bray-Curtis indices are calculated by pairs (in french "deux-àdeux") so we here compare pair X indices with pair Y indices

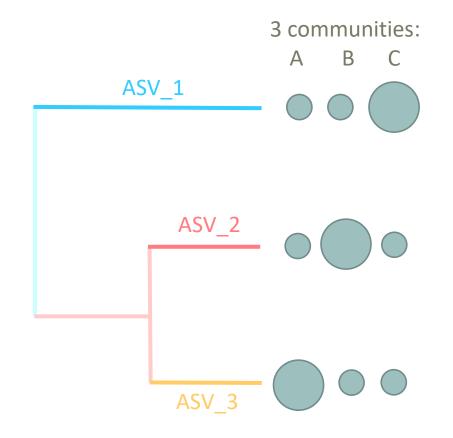

- Jaccard indices of X an Y are identical → same specific fraction (there are as many ASVs specific to Red or Blue1 in X, as there are ASVs specific to Red or Blue2 in Y).
- 2. Pair X: Bray-Curtis index is low because shared ASVs between Red and Blue1 communities are abundant and specific ASVs are at low abundance.
- 3. Pair Y: Bray-Curtis index is high because ASVs specific to Red or Blue2 are abundant and shared ASVs are at low abundance

3 ways to measure beta diversity with the same data set  $\rightarrow$  3 different results.

In this example :

- ✓ qualitatively, communities are very similar
- ✓ quantitatively, communities are very different
- phylogenetically, two communities seem to be closer than the third one.

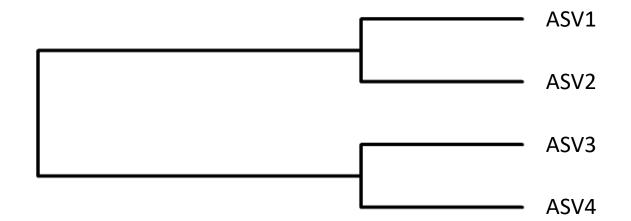

#### **Unifrac index**:

Fraction of <u>the tree</u> specific to either A or B

#### Weighted-Unifrac index :

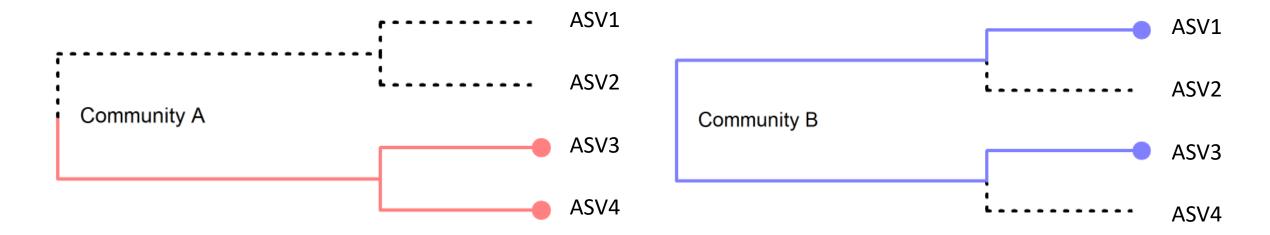

Fraction of the <u>diversity</u> specific to either A or B

**Unifrac index:** 

Fraction of <u>the tree</u> specific to either A or B

$$Unifrac = \frac{\sum specific\_branch\_length}{\sum all\_branch\_length}$$

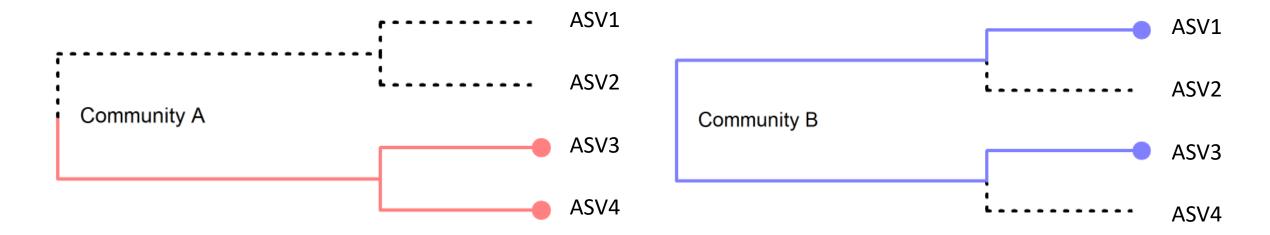

3 ASVs identified by sequencing: ASV3, ASV4 in community A and ASV1, ASV3 in community B

**Unifrac index:** 

Fraction of <u>the tree</u> specific to either A or B

$$Unifrac = \frac{\sum specific\_branch\_length}{\sum all\_branch\_length}$$

ASV1 and ASV4 are specific, ASV3 is shared in the 2 communities and ASV2 are absent in the 2 communities

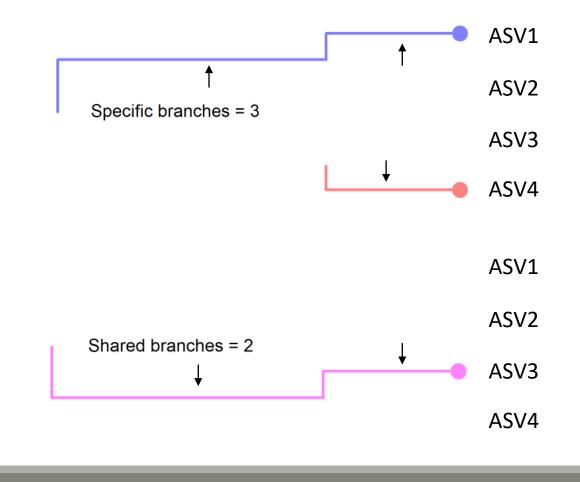

#### **Unifrac index**:

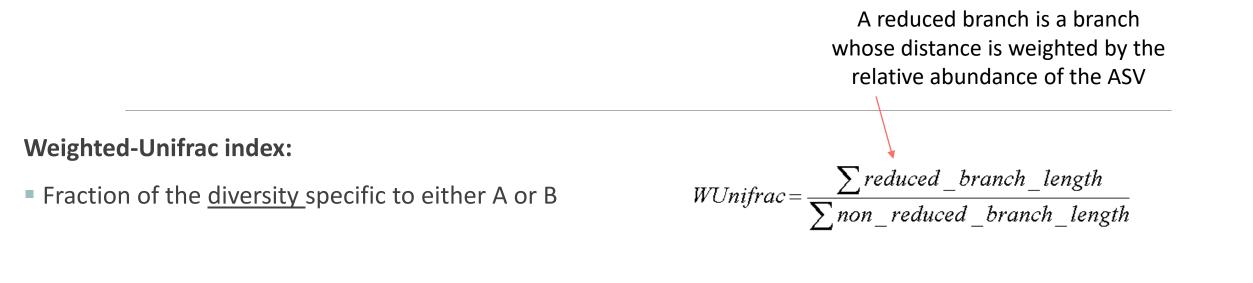

Fraction of <u>the tree</u> specific to either A or B

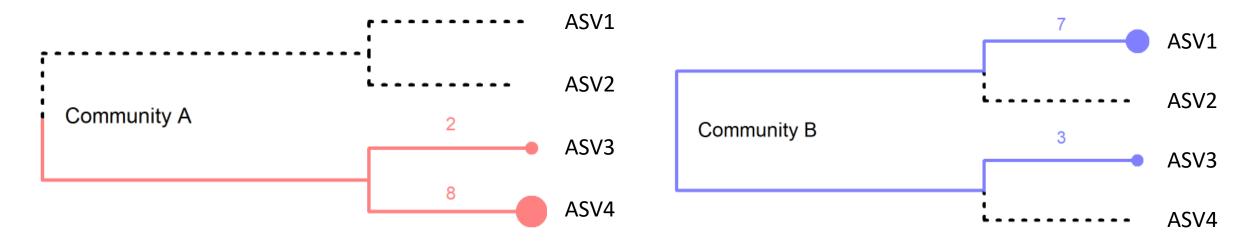

If all branch lengths are equal to 1, only branches present in at least one community are taken into account :

$$Unifrac = \frac{\sum specific\_branch\_length}{\sum all\_branch\_length} = 3/5 = 0.6$$

- Pink = common ASVs between the 2 communities
- Red= tree branch specific to A
- Blue= tree branch specific to B

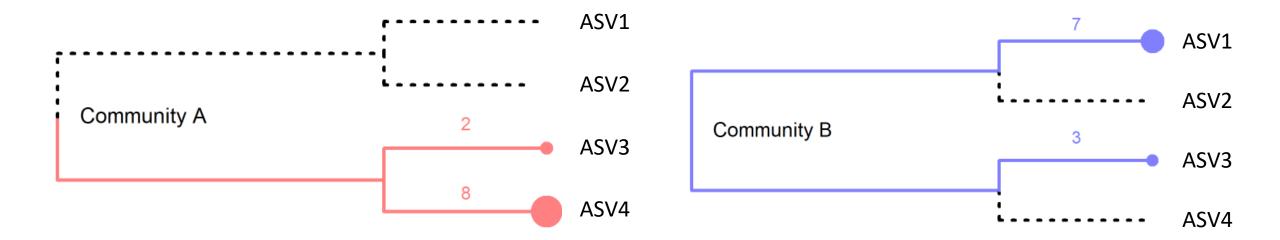

Weighted-Unifrac index:

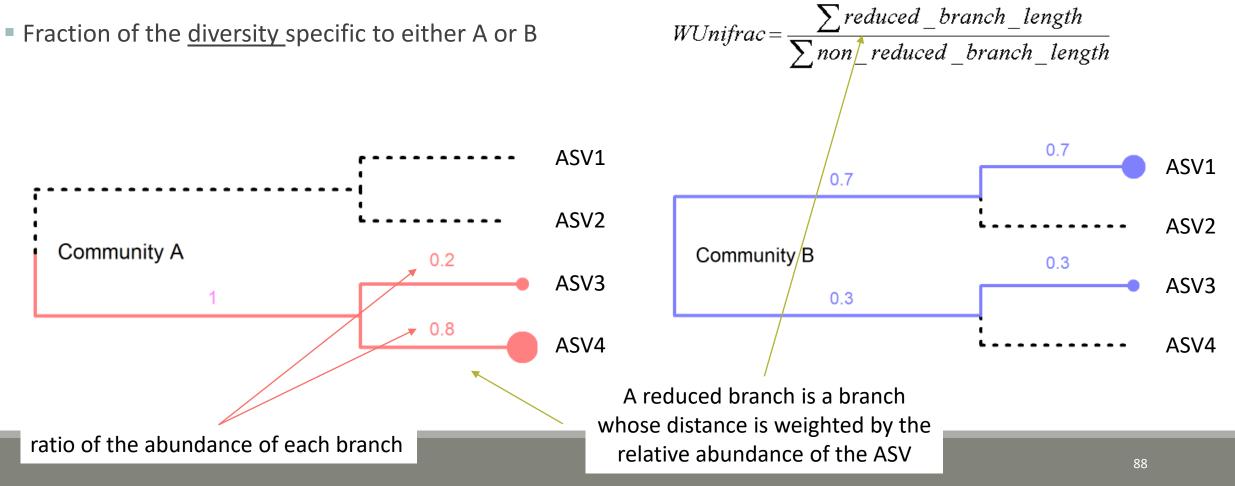

Fraction of the <u>diversity</u> specific to either A or B

$$WUnifrac = \frac{\sum reduced\_branch\_length}{\sum non\_reduced\_branch\_length}$$

Here the specific ASVs (ASV1 and ASV4) are the most abundant and are also the most phylogenetically distant.

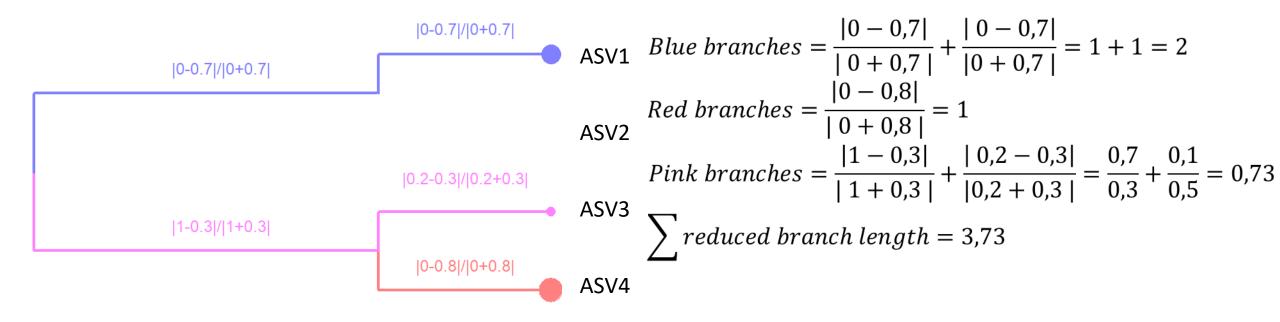

#### Weighted-Unifrac index:

Weighted-Unifrac index:

Fraction of the <u>diversity</u> specific to either A or B

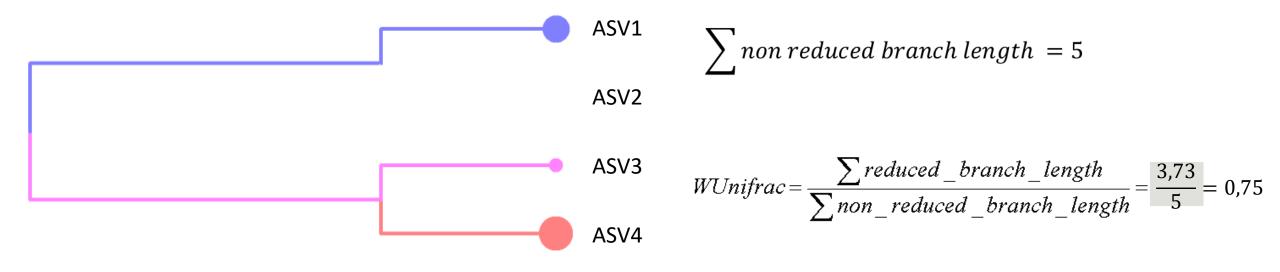

$$WUnifrac = \frac{\sum reduced\_branch\_length}{\sum non\_reduced\_branch\_length}$$

Weighted-Unifrac index:

Fraction of the <u>diversity</u> specific to either A or B

$$WUnifrac = \frac{\sum reduced\_branch\_length}{\sum non\_reduced\_branch\_length}$$

# Exploring biodiversity : $\beta$ -diversity in brief

qualitative indices: presence/absence regardless of abundance

quantitative indices: compare differences in abundance of ASVs

**phylogenetic** indices: integrate phylogenetic information to qualitative or quantitative indices (weighted or unweighted indices)

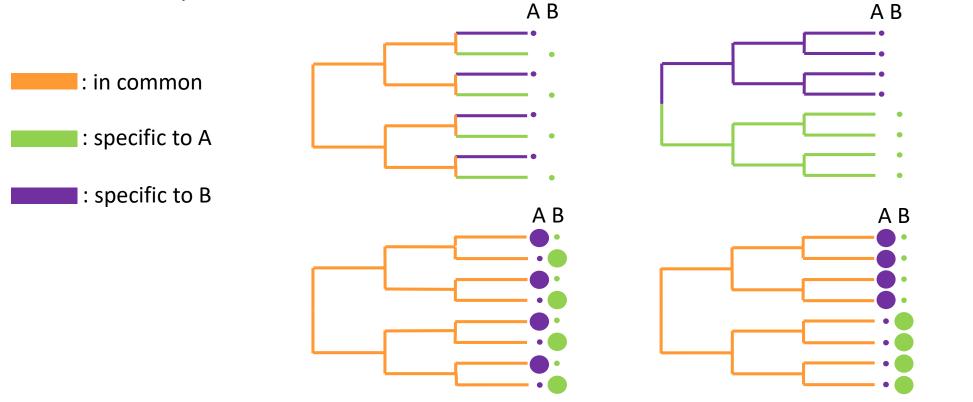

**Bray-Curtis** index : to evaluate the dissimilarity between two given samples, in terms of abundance of ASVs present in each sample. When Bray-Curtis index close to 0 means abundant ASVs are shared and in the same quantities between communities.

Jaccard index: beta diversity index, qualitative, takes into account the fraction of specific ASVs

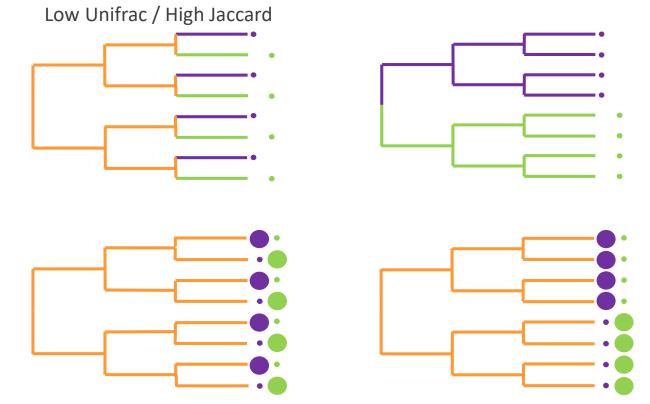

**Unifrac** index: beta diversity index, qualitative, takes into account the fraction of specific phylogenetic branches

Weighted-Unifrac index: beta diversity index, quantitative, takes into account the relative abundance of ASVs shared between samples

→ What do you conclude in terms of Jaccard, Bray Curtis, Unifrac and weigthed Unifrac values for these 4 pairs of communities?

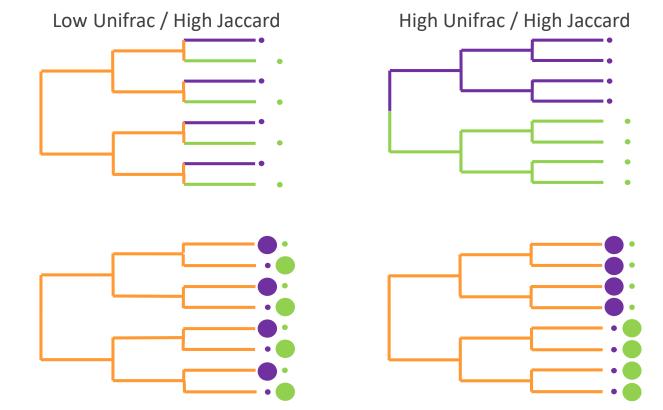

→ What do you conclude in terms of Jaccard, Bray Curtis, Unifrac and weigthed Unifrac values?

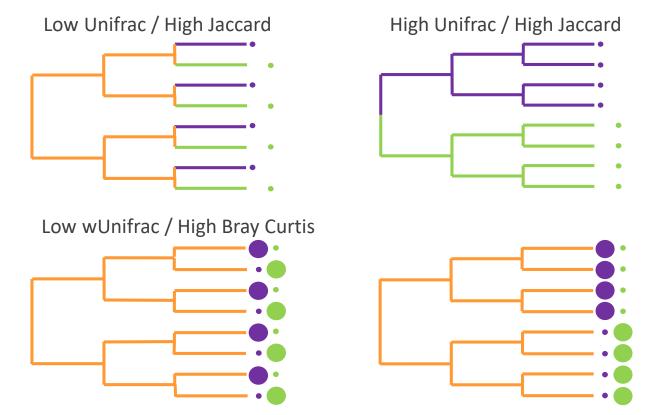

High Jaccard: same amount of specific ASVs Low Unifrac: small distance between specific branches

→ What do you conclude in terms of Jaccard, Bray Curtis, Unifrac and weigthed Unifrac values?

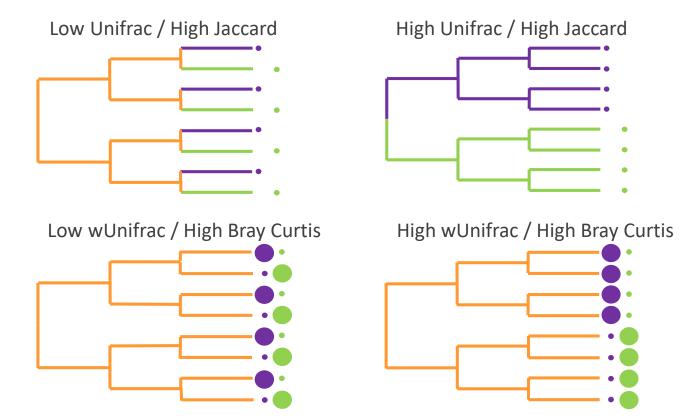

High Jaccard: all ASVs are specific to A or B High Unifrac: all the branches are specific to A or B

→ What do you conclude in terms of Jaccard, Bray Curtis, Unifrac and weigthed Unifrac values?

High Bray-Curtis: ASVs are shared but abundant ASVs are not the same in each community Low weighted-Unifrac: abundant ASVs in a community have a phylogenetically close relative in the other community

→ What do you conclude in terms of Jaccard, Bray Curtis, Unifrac and weigthed Unifrac values?

High Bray-Curtis: ASVs are shared but abundant ASVs are not the same in each community High weighted-Unifrac: abundant ASVs in a community are phylogenetically distant to any ASV in the other community

Phyloseq supports currently 43 beta diversity distance methods, (see <u>phyloseq distanceMethodList documentation</u>)

unifrac, wunifrac,

dpcoa, jsd, manhattan, euclidean, canberra,

bray, kulczynski, jaccard, gower, altGower, morisita, horn, mountford, raup, binomial chao, cao...

Other method	Tod can ask another beta diversity method
The other methods of beta diversity that you want to use (comma separated value). c.f. details below.	90

Try it with the 4 most commonly used distance methods

- 1. What are the output datasets ?
- 2. A priori, abundant ASVs are they shared among samples?
- 3. Comparing Jaccard and Unifrac, what can you conclude?
- 4. Comparing Unifrac and weighted Unifrac, what can you conclude?

1. What are the output files ?

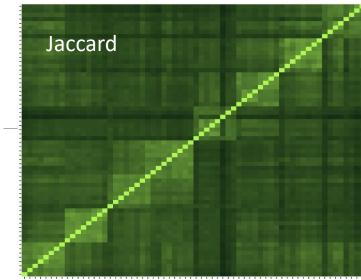

→ Tabular file: a tabular file per distance method containing the "all samples against all" matrix of beta diversity distance

 $\rightarrow$  HTML report: heatmap representing the distance matrix computed

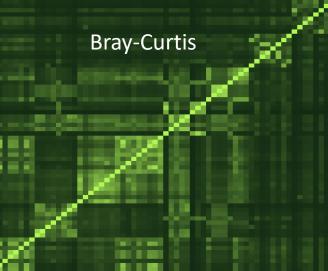

#### Heatmap plot of the beta distance : bray

Heatmap plot of the beta distance : cc

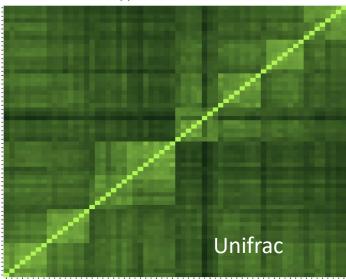

### Exercise 6

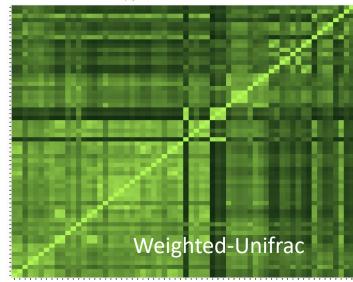

FROGSSTAT Phyloseq Beta Diversity: beta\_diversity.nb.html

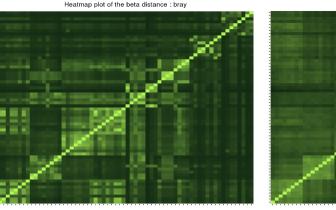

Heatmap plot of the beta distance : unifrac

Heatmap plot of the beta distance : wunifrac

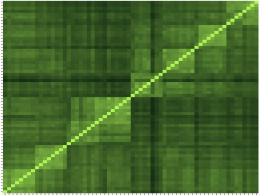

- Each square represents a comparison between 2 samples
- Lighter means more similar
- The diagonal represents the comparison of a sample with itself
- Along the diagonal we can spot clearer square structures
- We can assume that these are the different EnvTypes as the samples are ordered.

Heatmap plot of the beta distance : unifrac

**Bray-Curtis** 

Heatmap plot of the beta distance : wunifrac

Jaccard

Heatmap plot of the beta distance : cc

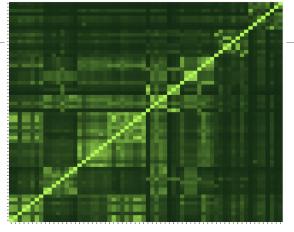

Unifrac

Weighted-Unifrac

#### 2. *A priori*, are abundant ASV shared among samples ?

#### **Bray-Curtis**

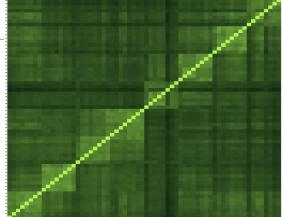

Heatmap plot of the beta distance : bray

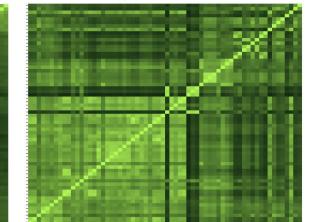

Heatmap plot of the beta distance : unifrac

Heatmap plot of the beta distance : cc

Heatmap plot of the beta distance : wunifrac

Weighted-Unifrac

2. *A priori*, are abundant ASV shared among samples ?

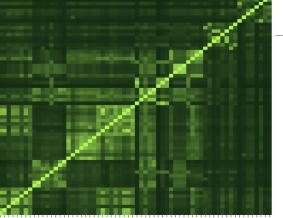

- Jaccard lower than Bray-Curtis
- Weighted-Unifrac is lower than Unifrac

→ The abundance accentuates the differences i.e. the distances are greater, i.e. the images are darker

→ abundant ASVs are community specific

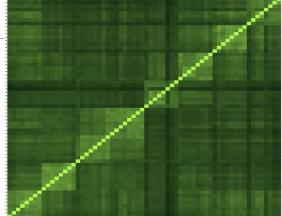

#### **Bray-Curtis**

Heatmap plot of the beta distance : bray

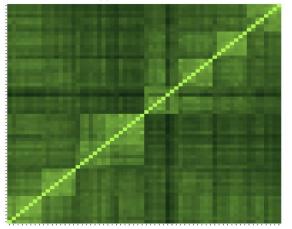

Jaccard

Heatmap plot of the beta distance : cc

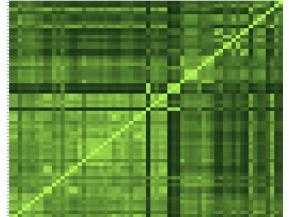

Heatmap plot of the beta distance : unifrac

Unifrac

Heatmap plot of the beta distance : wunifrac

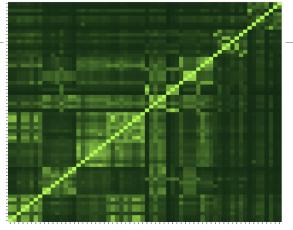

Weighted-Unifrac

3. Comparing Jaccard and Unifrac, what can you conclude ?

#### **Bray-Curtis**

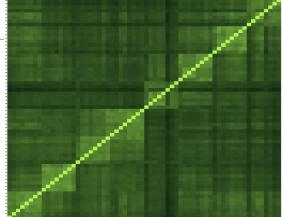

Heatmap plot of the beta distance : bray

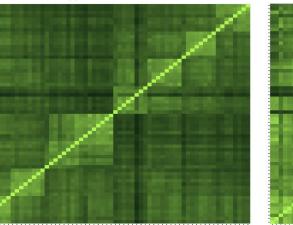

Heatmap plot of the beta distance : unifrac

Heatmap plot of the beta distance : cc

Heatmap plot of the beta distance : wunifrac

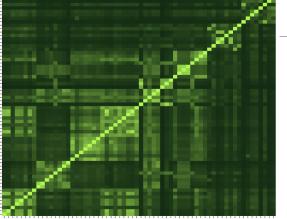

- 3. Comparing Jaccard and Unifrac, what can you conclude ?
- Jaccard and Unifrac are close.
- the phylogenetic distances do not accentuate the qualitative data of the Jaccard (neither darker, nor lighter), the species are thus close
- → ASVs are distinct but phylogenetically related

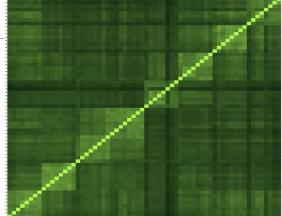

#### **Bray-Curtis**

Heatmap plot of the beta distance : bray

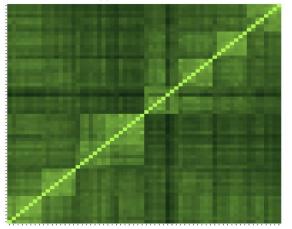

#### Jaccard

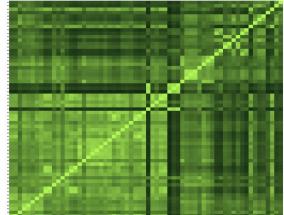

Heatmap plot of the beta distance : cc

Heatmap plot of the beta distance : unifrac

Heatmap plot of the beta distance : wunifrac

#### **Bray-Curtis**

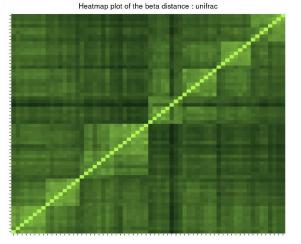

Heatmap plot of the beta distance : bray

Jaccard

Heatmap plot of the beta distance : cc

Heatmap plot of the beta distance : wunifrac

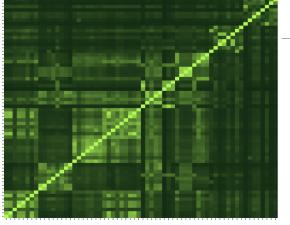

4. Comparing Unifrac and weighted Unifrac, what can you conclude ?

- Unifrac higher/darker than weighted Unifrac so distance between samples are more important
- taking into account the abundances makes the samples less distant (lighter)
- abundant ASVs in both communities are phylogenetically closed.

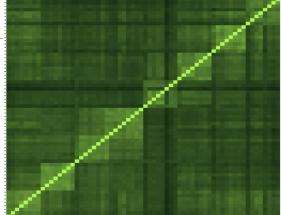

#### **Bray-Curtis**

Heatmap plot of the beta distance : bray

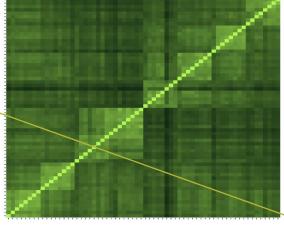

#### Jaccard

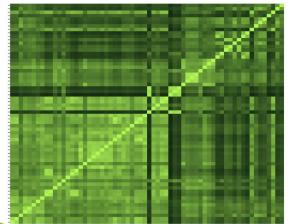

Heatmap plot of the beta distance : cc

Heatmap plot of the beta distance : unifrac

Heatmap plot of the beta distance : wunifrac

# Exploring biodiversity : $\beta$ -diversity

In general, qualitative diversities (Jaccard, Unifrac) are more sensitive to factors that affect presence/absence of organisms (such as pH, salinity, depth, etc) and therefore are useful to study and define bioregions (regions with little of no flow between them)...

•... whereas quantitative distances (Bray-Curtis, weighted-Unifrac) focus on factors that affect relative changes (seasonal changes, nutrient availability, concentration of oxygen, depth, etc.) and therefore useful to monitor communities over time or along an environmental gradient.

Different distances capture different features of the samples.

There is no "one size fits all"

# Exploring the structure

We will try to identify structures, relationships between samples related to environmental factors

# I. Structure Visualisation

#### ORDINATION AND HEATMAP PLOTS

We have calculated distances now, we will use ordination methods to explore them.

# Structure visualization : with PCA ?

Each community can be described by its ASV abundances, which could be used for a PCA, but high number of ASV make interpretations difficult

 Moreover, PCA maximizes variance and can therefore emphasize differences of rare ASVs between samples instead of giving a good representation of resemblances.
 Variance is not a very good measure of β-diversity.

PCA is not design to use diversity indices and/or distances as it requires independency between variables and does not fit to distance matrix, which is not constructed with samples and variables.

 $\beta$ -diversity indices thus required dedicated PCA-like methods.

**Purpose of the tool** : ordinate samples based on  $\beta$ -diversity indices and offer tools to visualize it: produce ordination plots and heatmaps.

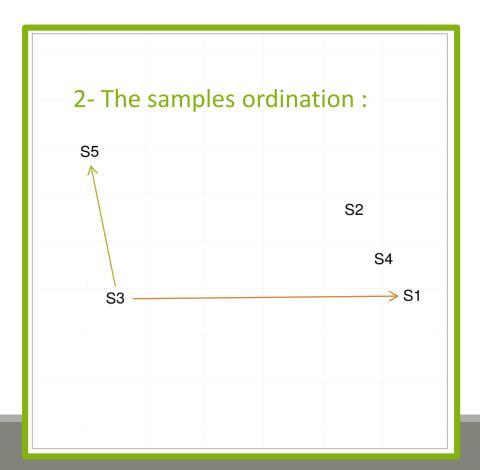

# Structure visualization : Ordination plot

The Multidimensional Scaling (**MDS** or **PCoA**) is equivalent to a Principal Component Analysis (PCA) but preserves the β-diversity instead of the variance.

The MDS tries to represent samples in two dimensions while preserving the distances

#### 1- calculation of a distance matrix.

	Distance Matrix					
	S1	S2	S3	S4	S5	
S1	0.00	2.21	6.31	0.99	7.50	
S2	2.21	0.00	5.40	1.22	5.74	
S3	6.31	5.40	0.00	5.75	3.16	
S4	0.99	1.22	5.75	0.00	6.64	
S5	7.50	5.74	3.16	6.64	0.00	

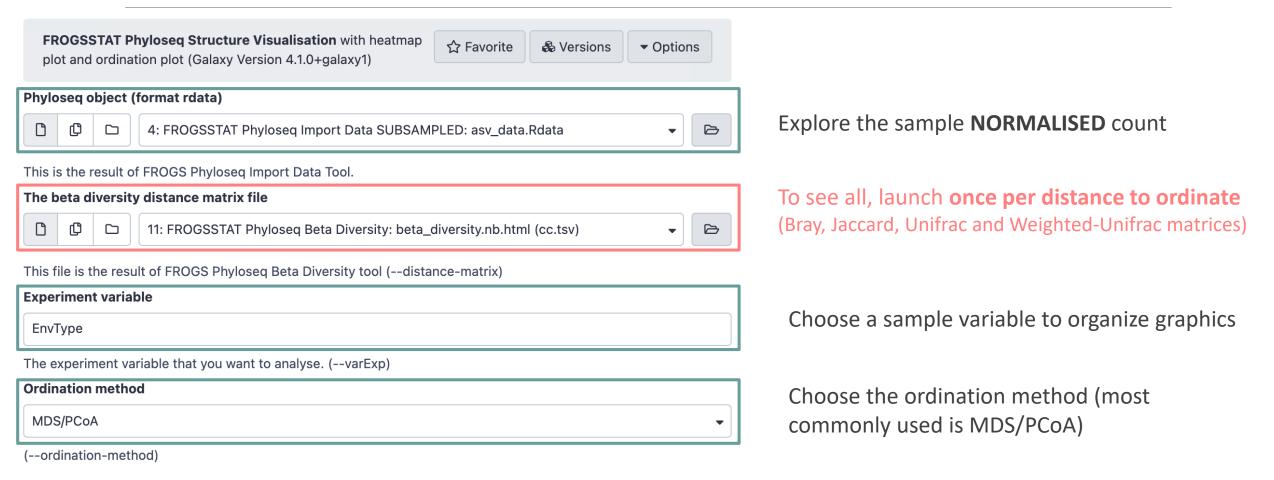

# Structure visualization : Heatmap

- Heatmap is an other representation of the abundance table.
- It tries to reveal if there is a structure between a group of ASVs and a group of samples.

Heatmap

- Finds a meaningful order of the samples and the ASVs
- Allows the user to choose a custom order (in R)
- Allows the user to change the colour scale (in R)
- Produces a ggplot2 object, easy to manipulate and customize

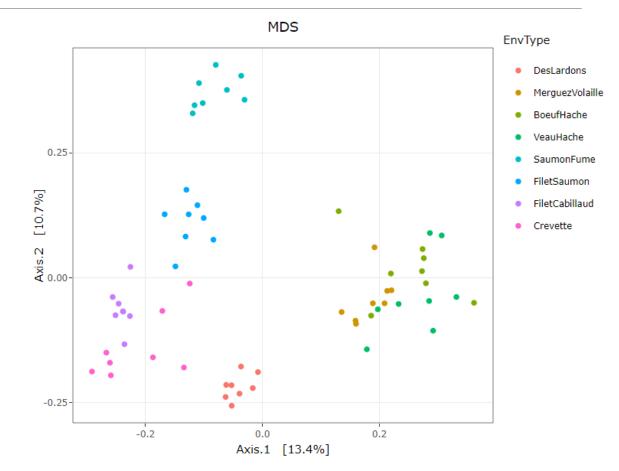

Try it with the 4 distance matrices

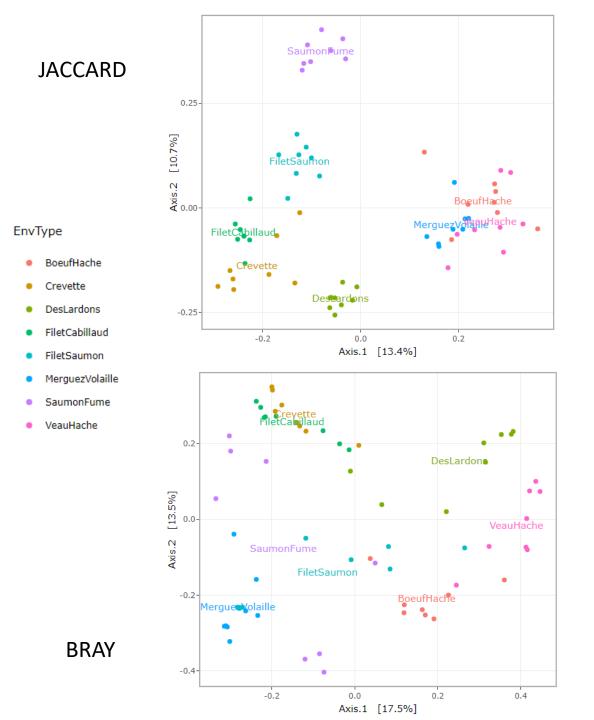

- 1. What are the output datasets ?
- 2. What is the best distance matrix to use to better separate samples ?
- 3. Guess why Lardon are somewhere between Meat and Seafood ?
- 4. Based on your favourite distance matrix, what can you conclude on the heatmap?

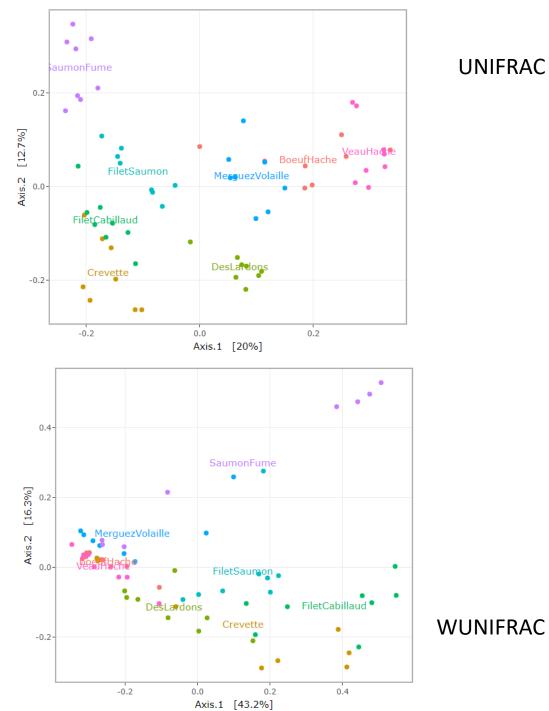

1. What are the output datasets ?

 $\rightarrow$  HTML report: ordination plot

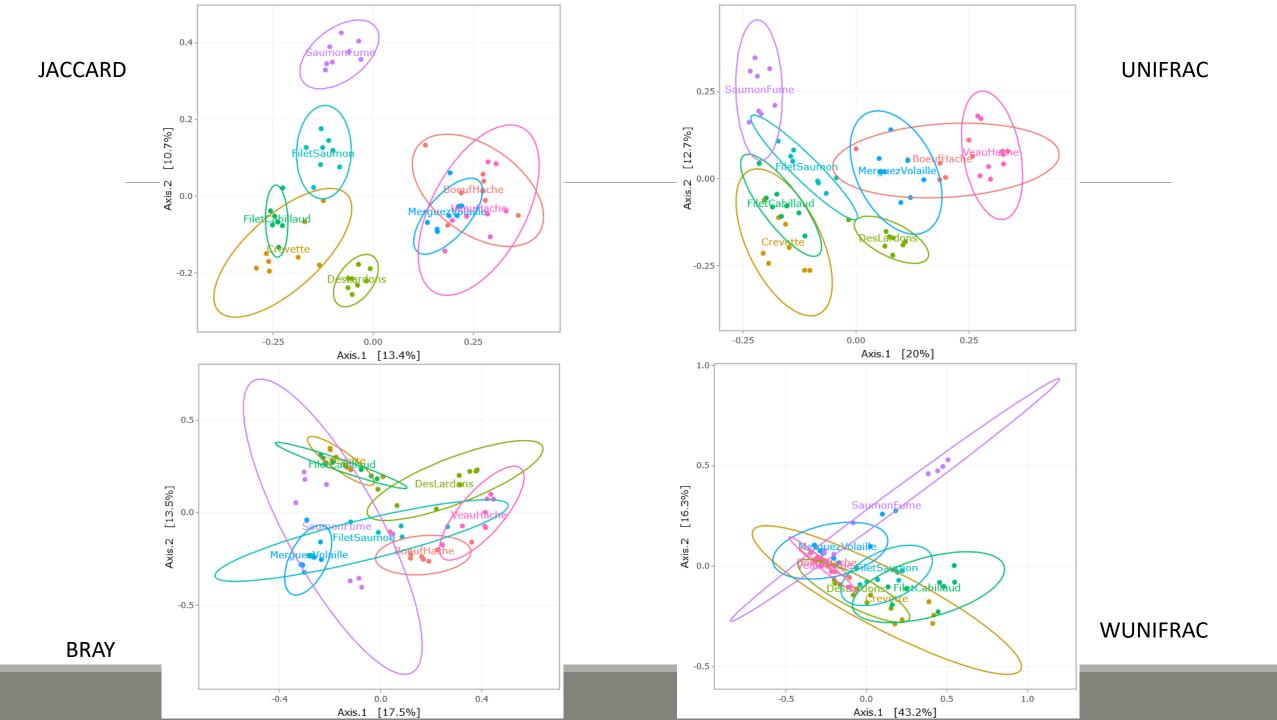

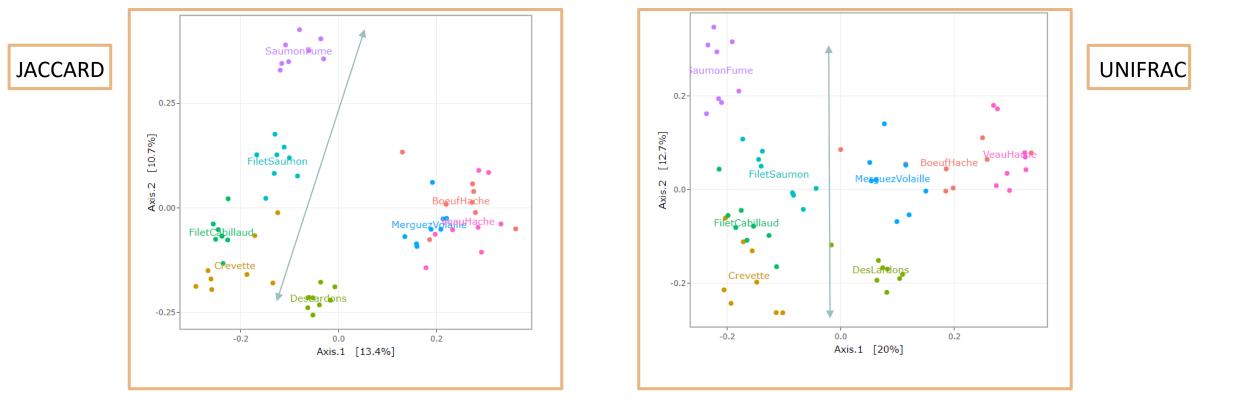

2. What is the best distance matrix to use to better separate samples ?

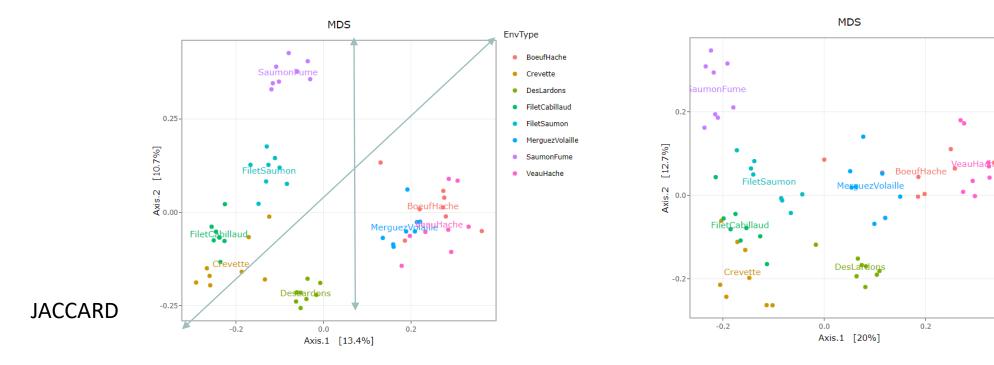

UNIFRAC

- Qualitative distances (Unifrac, Jaccard) separate meat products from seafood ones
- → detected taxa segregate by origin

#### 3. Guess why Lardon are somewhere between Meat and Seafood ?

UNIFRAC

EnvType

BoeufHache

DesLardons

FiletCabillaud

FiletSaumon

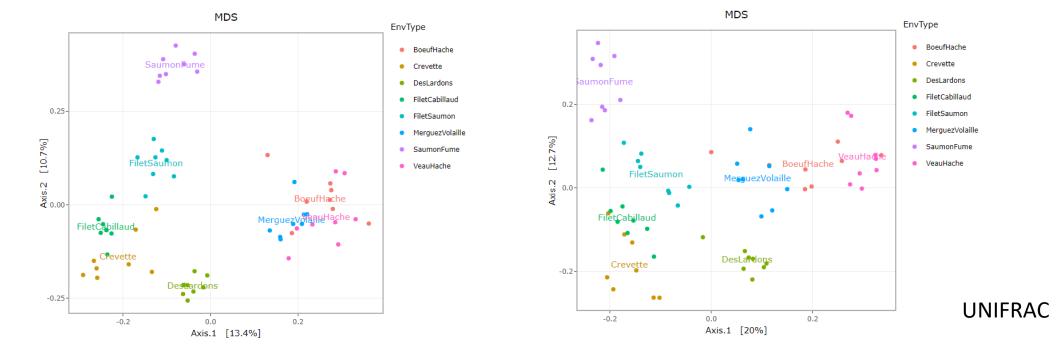

SaumonFume

VeauHache

MerguezVolaille

Crevette

#### 3. Guess why Lardon are somewhere between Meat and Seafood ?

DesLardons is somewhere in between

JACCARD

 $\rightarrow$  contamination induced by sea salt

Other conclusions ?

1. Quantitative distances (weighted Unifrac ) exhibit a 'meat – seafood' gradient (on axis 1) with DesLardons in the middle and a 'SaumonFume - everything else' gradient on axis 2.

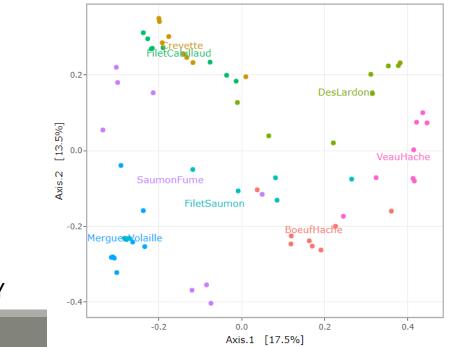

Other conclusions ?

2. Note the difference between weighted-UniFrac and Bray-Curtis (2 quantitative indices) for the distances between BoeufHache and VeauHache.

Other conclusions ?

3. On Bray-Curtis, on axis 2, we can observe the distribution of Saumon Fumé samples. Axis 1 shows the distribution of MerguezdeVolaille samples

BRAY

Other conclusions ?

The 2D representation captures only parts of the original distances

Ellipse are not always an advantage for visualization because it accentuates the 2D effect

4. Based on your favourite distance matrix, what can you conclude on the **heatmap**?

Try to identify:

- Block-like structure of the abundance table
- Interaction between (groups of) taxa and (groups of) samples
- Core and condition-specific microbiota

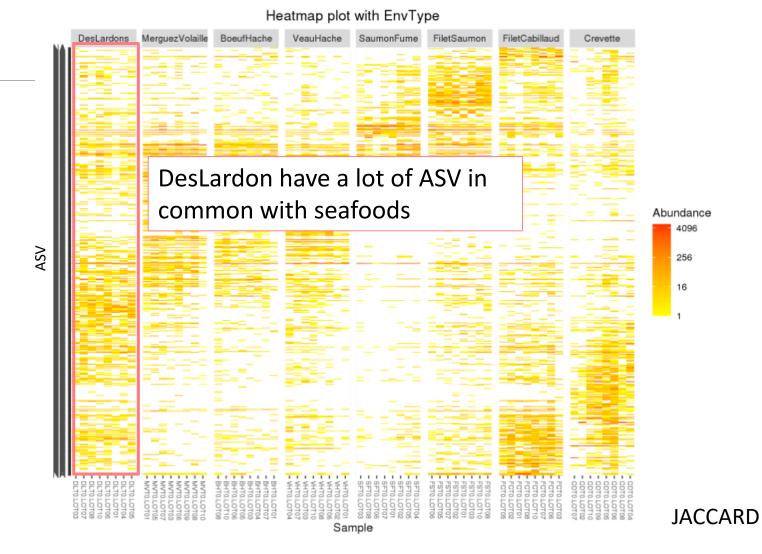

4. Based on your favourite distance matrix, what can you conclude on the heatmap ?

matrix based on Jaccard distance (qualitative) which "sorts" the ASVs. Then a color is applied according to the abundance of ASVs (yellow to red).

#### DesLardons MerquezVolaille SaumonFume FiletCabillaud FiletSaumon Crevette ASV shared by all samples Abundance 4096 ASV 256 16 JACCARD Sample

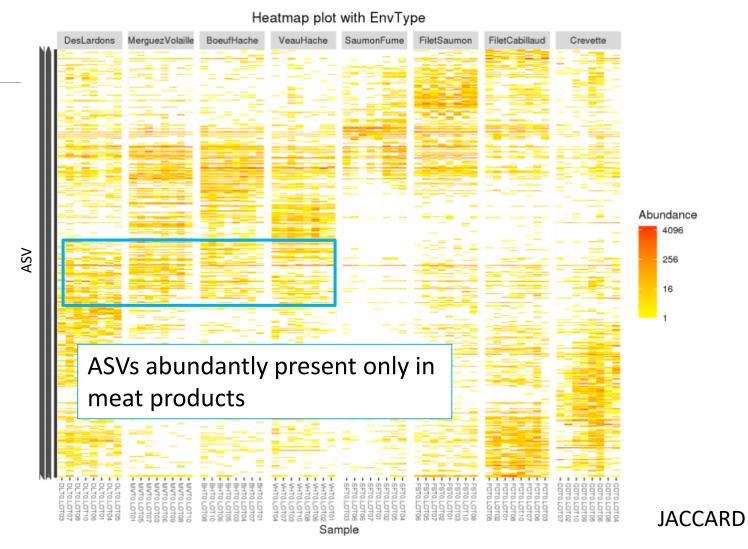

Heatmap plot with EnvType

4. Based on your favourite distance matrix, what can you conclude on the heatmap ?

4. Based on your favourite distance matrix, what can you conclude on the heatmap ?

Note: no evidence for seafood.

# II. Exploring the structure

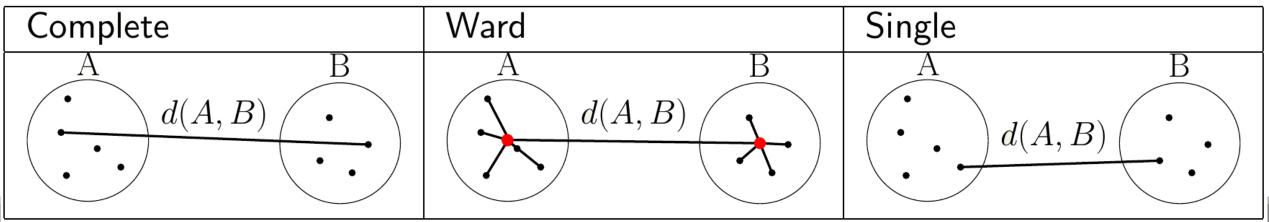

HIERARCHICAL CLUSTERING

# Exploring the structure : clustering

Clustering aims to represent samples in a tree based on a distance matrix and a linkage function:

3 clustering algorithms:

- Complete linkage: tends to produce compact, spherical clusters and guarantees that all samples in a cluster are similar to each other.
- Ward: tends to also produce spherical clusters but has better theoretical properties than complete linkage.
- Single: friend of friend approach, tends to produce banana-shaped or chains-like clusters.

# Exploring the structure : clustering

The experiment variable that you want to analyse. (varExp)	

The three different linkage functions will be used, generating three different dendrograms

134

Try it with « a good » distance method matrix on EnvType and on FoodType

→ Which linkage method seems to better fit the data ?

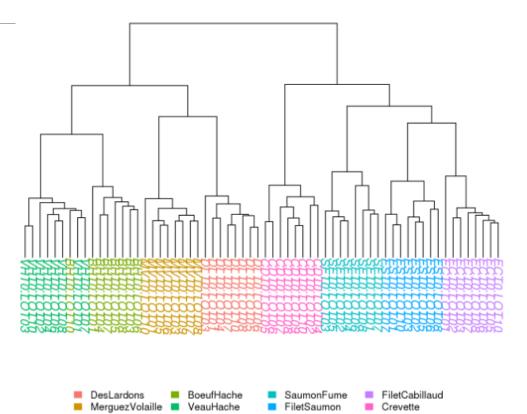

the Ward clustering allows to classify the communities according to the EnvType groups

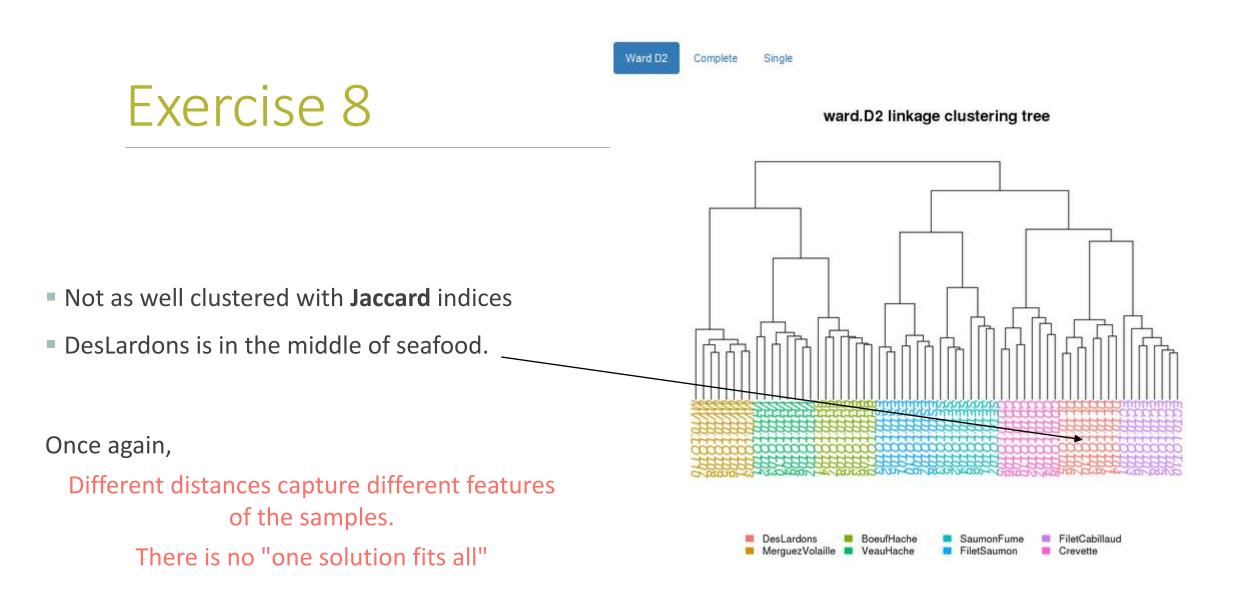

- Consistently, for these datasets, with the ordination plots, clustering works quite well for the UniFrac distance
- The method (Ward.D2) give almost a perfect separation between the different type of food

#### <u>Remarks</u>

Clustering is based on the whole distance whereas ordination represents parts of the distance (the most it can with 2 dimensions)

#### ward.D2 linkage clustering tree

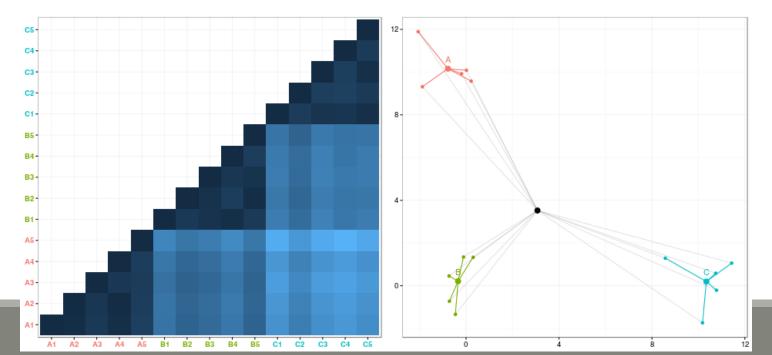

# Diversity partitioning

# Diversity partitioning

Do the structures seem linked to metadata ? Does the metadata have an effect on the composition of our communities ?

To answer these questions, **multivariate analyses** :

- test composition differences of communities from different groups using a distance matrix
- compare within-group to between-group distances

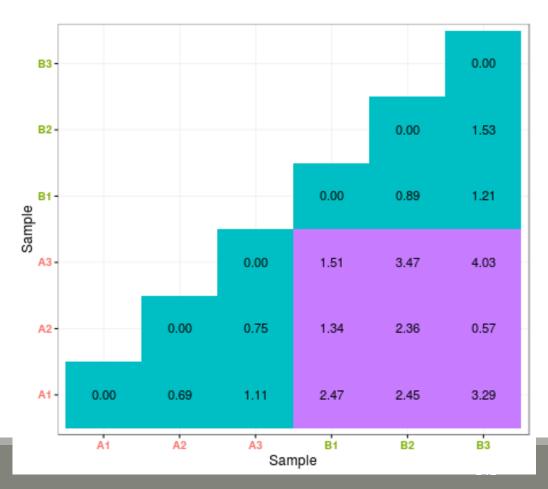

# Diversity partitioning : Multivariate ANOVA

Idea : Test differences in the community composition from different groups using a distance matrix.

How it works ?

- Computes sum of square distance
- Variance analysis

# Diversity partitioning : Multivariate ANOVA

FROGSSTAT DESeq2 Visualisation to extract and visualise differentially abundant         ASVs or functions (Galaxy Version 4.1.0+galaxy1)												
Type of analysis												
⊘ ASV O FUNCTION	Ask for DESeq2 ASV data analysis											
Type of data to perform the differential analysis. ASV: DESeq2 is run on the ASV abundance table. FUNCTION: DESeq2 is run on predicted function abundance table from FROGSFUNC_2_function tool.												
Data object (format: data.RData)												
Image:	Result of FROGSSTAT DESeq2 preprocess											
For ASV: asv_data.Rdata from FROGSSTAT_Phyloseq_Import_Data tool - For FUNCTION: function_data.Rdata from FROGSSTAT_DESeq2_Preprocess tool. (abundanceData)												
DESeq2 object (format: dds.RData)	Factor on which the differential											
Image: Constraint of the second se	abundances have been tested											
This is the result of FROGSSTAT_DESeq2_Preprocess tool asv_dds.Rdata or function_dds.Rdata (dds)												

Experimental variable	Factor on which the differential
ЕпѵТуре	abundances have been tested
The factor that could have an effect on ASV/FUNCTION abundances. Ex : Treatment (var)	
The experimental variable is it quantitative or qualitative?	
Qualitative	Specify qualitative or quantitative
If qualitative, choose 2 conditions to compare	
Condition 1 considered as reference	
BoeufHache	Dracica tha two conditions to compare
One condition of the experimental variable (e.g. with) (mod2)	Precise the two conditions to compare
Condition 2 to be compared to the reference	
VeauHache	
Another condition of the experimental variable (e.g. without) (mod1)	
Adjusted p-value threshold	Statistical significance throshold
0.05	Statistical significance threshold (default 0.05)
Threshold used for statistical significance of the differentially abundant ASV/FUNCTION analysis (padj)

MA plot Heatmap plot

Code

You chose to compare VeauHache to the reference modality BoeufHache. This implies that a positive log2FoldChange means more abundant in VeauHache than in BoeufHache.

Code

Then we extract significant ASVs or FUNCTIONs at the p-value adjusted threshold (after Benjamini Hochberg correction) and enrich results with taxonomic/functional classification and sort the results by pvalue.

Why log2Foldchange?

Differentially abundant ASV/FUNCTION table

### Foldchange:

It's the ratio of the normalized counts between VeauHache and BoeufHache

log2 is used for interpret and scale reasons:

- Positive values denote an increase, and negative a decrease of abundance
- log2FC = 1 means a doubling
- log2FC = 2 means a quadrupling
- log2FC = -1 means a halving
- log2FC = -2 means a quartering

...

#### Pie chart

Differentially Abundant (log-fold change < 0) Differentially Abundant (log-fold change > 0) Not Differentially Abundant

Most of the ASVs are not significantly affected between the conditions (DESeq2 hypothesis !!)

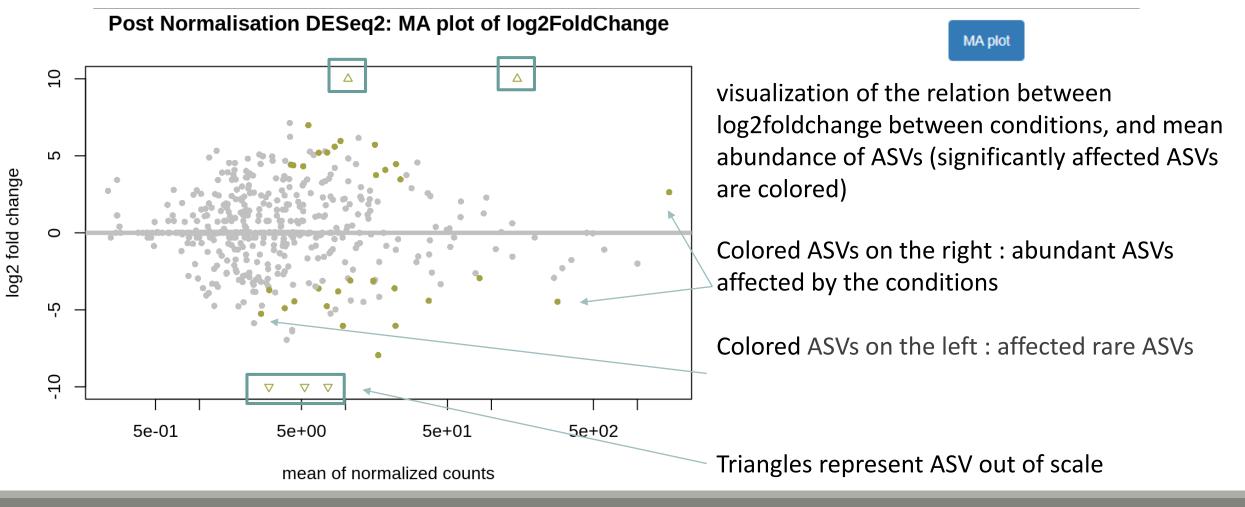

35 ASVs are significantly affected between conditions

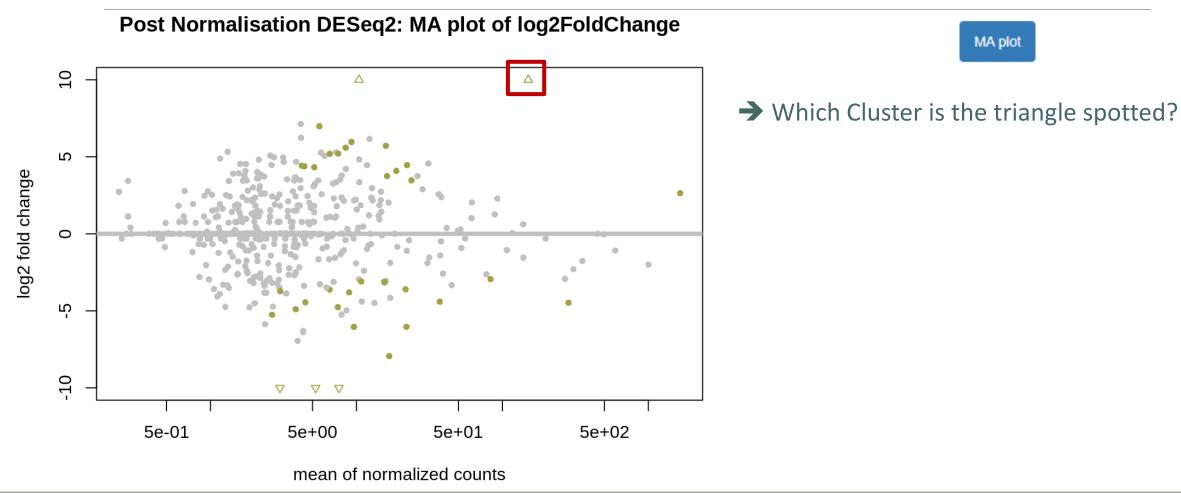

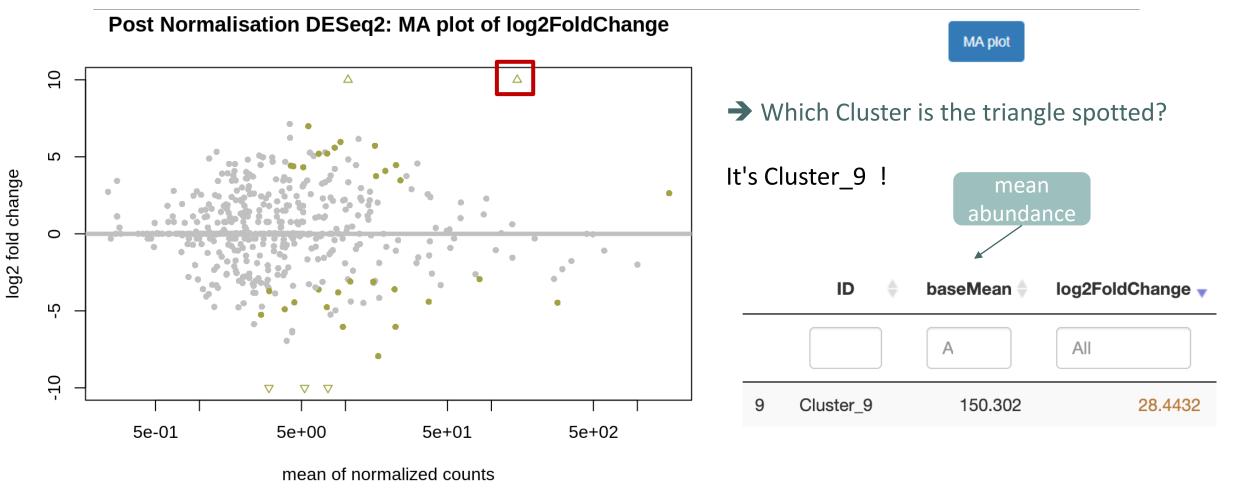

#### Volcano plot

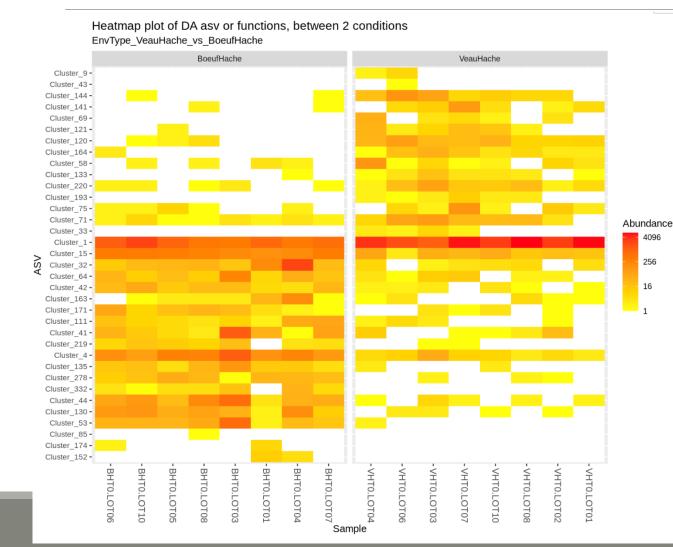

visualization of ASVs log2FoldChange and their associated adjusted p-values

Only ASVs with a significant adjusted p-value are colored

#### Heatmap plot

visualization of the DESeq2 normalised abundances of differentially abundant ASVs grouped by condition

Here, we observe only the significant 35 ASV that are differential abundant

### ASVs are ordered from top to bottom in log2 flold change descending order

### Compare FiletSaumon vs SaumonFume

#### **Experimental variable**

EnvType

The factor that could have an effect on ASV/FUNCTION abundances. Ex : Treatment (var)

#### The experimental variable is it quantitative or qualitative?

Qualitative

If qualitative, choose 2 conditions to compare

 Condition 1 considered as reference

 FiletSaumon

 One condition of the experimental variable (e.g. with) (--mod2)

 Condition 2 to be compared to the reference

 SaumonFume

 $\mathbf{T}$ 

Another condition of the experimental variable (e.g. without) (--mod1)

Differentially abundant ASV/FUNCTION table

Pie chart

Volcano plot MA plot

Heatmap plot

Since we only have a binary factor we can use the following syntax to format the log2 fold change from the litted model if not, we will use the other syntax with contrast=c()

You chose to compare SaumonFume to the reference modality FiletSaumon. This implies that a positive log2FoldChange means more abundant in SaumonFume than in FiletSaumon.

Then we extract significant OTUs at the p-value adjusted threshold level (after correction) and enrich results with taxonomic informations and sort taxa by pvalue.

# Conclusion and advices reminder

### FROGSTAT advices

- Before starting, check taxonomy format : how many levels? What are their names ?
- Carefully construct your sample\_metadata TSV file, and after its import, check that your variable order is smart
- Keep in mind that :
  - Phyloseq composition and structure analyses need to be perform on normalised (=rarefied) counts
  - DESeq analysis needs to be performed on counts without normalisation
  - Different indices or distance methods will give different but complementary information
  - Test different distances and choose which one fits better your data
